Contents

1	Introduction to this book	10
2	Introduction to DFT	12
2.1	Background	13
2.2	Exchange correlation functionals	14
2.3	Basis sets	14
2.4	Pseudopotentials	16
2.5	Fermi Temperature and band occupation numbers	16
2.6	Spin polarization and magnetism	17
2.7	TODO Recommended reading	17
3	Molecules	18
3.1	Defining and visualizing molecules	18
3.1.1	From scratch	18
3.1.2	Reading other data formats into a calculation	21
3.1.3	Predefined molecules	23
3.1.4	Combining Atoms objects	28
3.2	Simple properties	29
3.2.1	Getting cartesian positions	29
3.2.2	Molecular weight and molecular formula	30
3.2.3	Center of mass	31
3.2.4	Moments of inertia	31
3.2.5	Computing bond lengths and angles	33
	Dihedral angles	35
3.3	Simple properties that require computations	36
3.3.1	Energy and forces	36
	Convergence with unit cell size	36
	Convergence of ENCUT	38
3.3.2	The density of states (DOS)	39
3.3.3	Atom-projected density of states on molecules	40
3.3.4	Visualizing electron density	42
3.3.5	TODO Electrostatic potential	45
3.3.6	Dipole moments	46
3.3.7	Bader analysis	48

3.4	Geometry optimization	51
3.4.1	Bond lengths	51
	Manual determination	51
	Automatic geometry optimization with VASP	54
	Relaxation of a water molecule	55
3.5	Vibrational frequencies	55
3.5.1	Manual calculation of vibrational frequency	55
3.5.2	Automated vibrational calculations	57
	Zero-point energy for multiple modes	59
3.6	Simulated infrared spectra	59
3.7	Thermochemical properties of molecules	63
3.8	Molecular reaction energies	65
3.8.1	O ₂ dissociation	65
	Simple estimate of O ₂ dissociation energy	65
	Estimating O ₂ dissociation energy with spin polarization in triplet ground states	66
	Looking at the two spin densities	67
	Convergence study of the O ₂ dissociation energy	68
	Illustration of the effect of SIGMA	70
	Estimating triplet oxygen dissociation energy with low symmetry	72
	Estimating singlet oxygen dissociation energy	75
	Verifying the magnetic moments on each atom	76
	Using a different potential	77
3.8.2	Water gas shift example	78
	Calculation summaries	80
	CO	80
	CO ₂	81
	H ₂	82
	H ₂ O	83
3.8.3	Temperature dependent water gas shift equilibrium constant	84
	CO vibrations	84
	CO ₂ vibrations	85
	H ₂ vibrations	85
	H ₂ O vibrations	86
	TODO Thermochemistry	86
	TODO something is wrong with the thermochemistry I think.	89
3.9	Molecular reaction barriers	89
3.9.1	Get initial and final states	89
3.9.2	Run band calculation	90
4	Bulk systems	91
4.1	Defining and visualizing bulk systems	92
4.1.1	Built-in functions in ase	92
4.1.2	Using http://materialsproject.org	92
4.2	Determining bulk structures	95
4.2.1	fcc/bcc crystal structures	96

4.2.2	hcp	100
4.2.3	Complex structures with internal degrees of freedom	102
4.2.4	TODO the volume is very small (61) compared to what we expected (64) something may be wrong!	108
4.3	Effect of calculation parameters on bulk calculations	108
4.3.1	TODO k-point convergence ?	108
4.3.2	Effect of SIGMA	108
4.4	Cohesive energy	110
4.5	Effect of pressure on phase stability	112
4.6	Bulk reaction energies	117
4.6.1	Alloy formation energies	117
	Basic alloy formation energy	117
4.6.2	Metal oxide oxidation energies	124
	Cu ₂ O calculation	124
	CuO calculation	126
	Reaction energy calculation	127
4.7	Bulk density of states	128
4.8	Atom projected density of states	130
4.8.1	Effect of RWIGS on ADOS	133
4.9	Band structures	135
4.9.1	TODO create example showing band dispersion with lattice constant . .	137
4.10	Magnetism	137
4.10.1	Determining if a magnetic solution is energetically favorable	137
4.10.2	Antiferromagnetic spin states	139
4.10.3	TODO NiO-FeO formation energies with magnetism	140
4.11	TODO phonons	140
4.12	TODO solid state NEB	140
5	Surfaces	140
5.1	Surface structures	140
5.1.1	Simple surfaces	140
5.1.2	Vicinal surfaces	141
5.2	Surface relaxation	144
5.3	Surface reconstruction	147
5.3.1	Au(110) missing row reconstruction	147
	Clean Au(110) slab	147
	Missing row in Au(110)	149
	Bulk Au	150
	Analysis of energies	151
5.3.2	Ag(110) missing row reconstruction	151
	Clean Ag(110) slab	151
	Missing row in Ag(110)	152
	Bulk Ag	152
	Analysis of energies	152
5.4	Work function	153
5.5	Surface energy	154

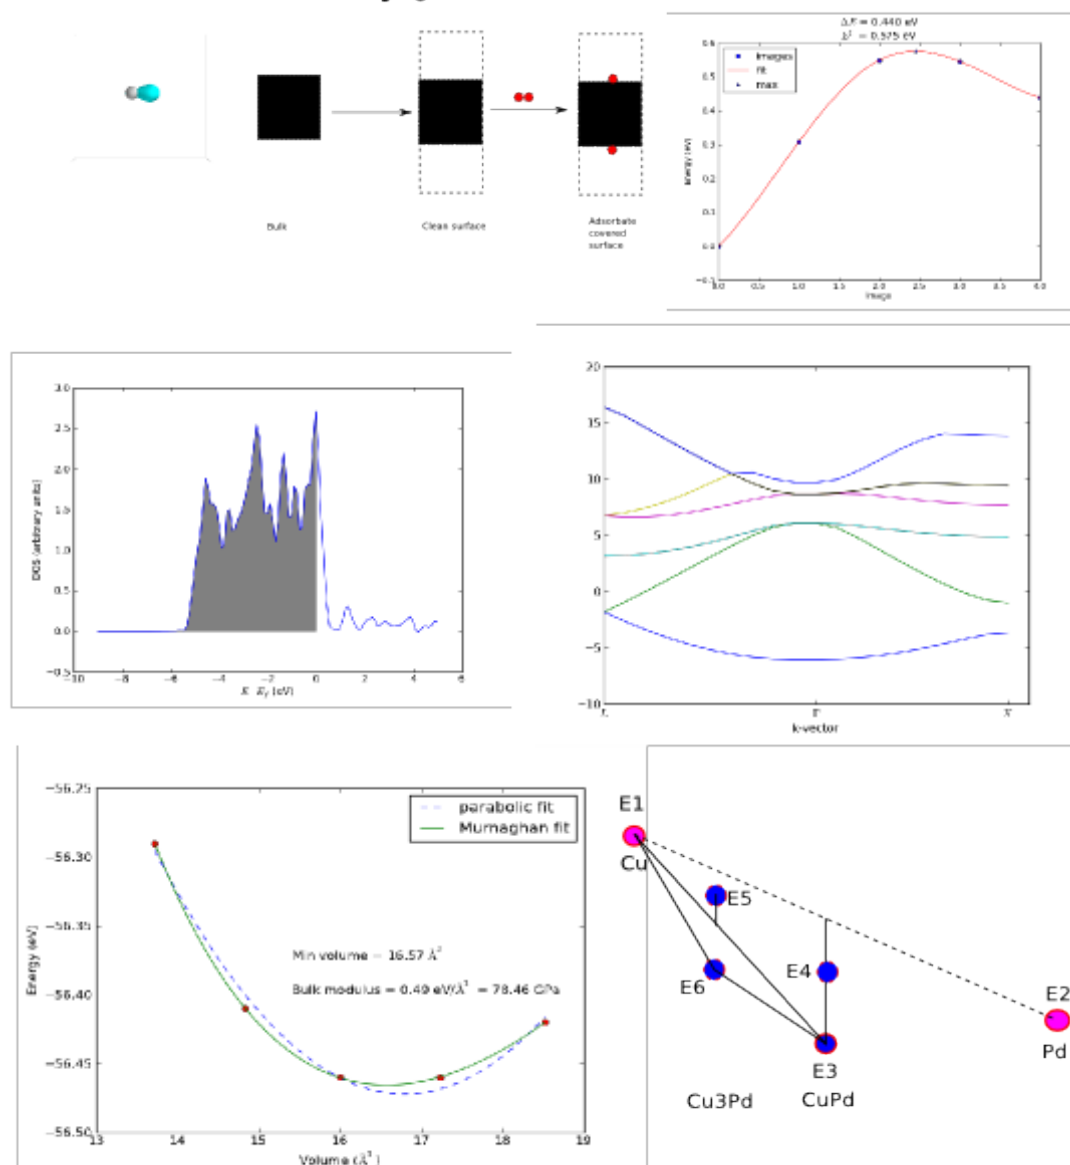

5.5.1	Advanced topics in surface energy	157
5.6	Dipole correction	158
5.6.1	Slab with no dipole correction	158
5.6.2	Slab with a dipole correction	158
5.6.3	Comparing no dipole correction with a dipole correction	159
5.7	Adsorption energies	161
5.7.1	Simple estimate of the adsorption energy	161
	Calculations	161
	clean slab calculation	161
	fcc site	161
	bridge site	162
	hcp site	162
	Analysis of adsorption energies	163
	Adsorption on bridge site with constraints	166
5.7.2	Coverage dependence	167
	clean slab calculation	168
	fcc site at 1 ML coverage	168
	Adsorption energy at 1ML	168
5.7.3	Effect of adsorption on the surface energy	169
5.8	Adsorbate vibrations	170
5.8.1	Vibrations of the bridge site	171
5.9	Surface Diffusion barrier	172
5.9.1	Standard nudged elastic band method	172
5.9.2	Climbing image NEB	173
5.9.3	TODO use vibrations to confirm transition state	175
5.10	TODO Diffusion rates with transition state theory	175
5.11	TODO Simulating STM images	175
6	Atomistic thermodynamics	175
6.1	Bulk phase stability of oxides	177

5	Adsorption site dependence of adsorption energies of oxygen on Pt(111).	182
6	Meaning of extensions on POTCAR files for special setups.	229

1 Introduction to this book

This book serves two purposes: 1) to provide worked examples of using DFT to model materials properties, and 2) to provide references to more advanced treatments of these topics in the literature. It is not a definitive reference on density functional theory. Along the way to learning how to perform the calculations, you will learn how to analyze the data, make plots, and how to interpret the results. This book is very much “recipe” oriented, with the intention of giving you enough information and knowledge to start your research. In that sense, many of the computations are not publication quality with respect to convergence of calculation parameters.

You will read a lot of python code in this book, as the comprehension of code is an integral part of its design. I believe that computational work should always be scripted. As a result, a written record of everything you have done will be available, allowing you to reproduce your code or report the method of its execution exactly at a later time.

This book makes heavy use of many computational tools including:

- [Python](#)
 - [Module index](#)
- [Atomic Simulation Environment \(ase\)](#)
- [numpy](#)
- [scipy](#)
- [matplotlib](#)
- [emacs](#)
 - [org-mode](#) This book is written in org-mode, and is best read in emacs in org-mode. This format provides clickable links, easy navigation, syntax highlighting, as well as the ability to interact with the tables and code. The book is also available in PDF.
- [git](#) This book is available at <https://github.com/jkitchin/dft-book>
- [jasp](#)

`jasp` is a sophisticated wrapper to the `ase.calculators.vasp` python interface to the VASP calculator. It was written by me to facilitate writing this book and to develop the best possible way to run DFT calculations. The best way to learn to use `jasp` is from this book. `jasp` is currently available at <https://bitbucket.org/jkitchin/jasp>. It probably requires the latest svn version of ase to work since I have been adding new functionality to `ase.calculators.vasp` as `jasp` is developed.

The goal in writing `jasp` was to create a computational environment where you write one script to create, run and analyze your calculations. The code is smart, and submits jobs to a queue system when required, does not submit jobs more than once, allows many jobs to run in parallel, and gives you answers when available. `jasp` takes care of changing into VASP calculation directories, and then changing back to where you started from. `jasp` has an interface to sqlite, and to version control (git) software. `jasp` has some features that `ase.calculators.vasp` does not have yet. They may get incorporated into ase one day.

`jaspsum` is a utility program provided in `jasp` which prints a pretty representation of the state of a calculation, plots the relaxation trajectory, or prints a code representation of a vasp directory.

It is not critical that you use `jasp`. You should be able to copy the actual VASP input files (which were generated by `jasp`) from a directory and simply run vasp. `jasp` is mostly compatible with `ase.calculators.vasp`, so you can replace this kind of code:

```
1 with jasp('directory', lotsofkeywords, atoms=atoms) as calc:
2     #do stuff
```

with code similar to this:

```
1 CWD = os.getcwd()
2 os.chdir('directory')
3 calc=Vasp(lotsofkeywords)
4 atoms.set_calculator(calc)
5
6 try:
7     #do stuff
8 finally:
9     os.chdir(CWD)
```

The DFT code used primarily in this book is [VASP](#).

- [VASP wiki](#)
- [VASP Manual](#)

Similar code would be used for other calculators, e.g. GPAW, Jacapo, etc... you would just have to import the python modules for those codes, and replace the code that defines the calculator.

Exercise 1.1

Review all the hyperlinks in this chapter.

2 Introduction to DFT

A comprehensive overview of DFT is beyond the scope of this book, as excellent reviews on these subjects are readily found in the literature, and are suggested reading in the following paragraph. Instead, this chapter is intended to provide a useful starting point for a non-expert to begin learning about and using DFT in the manner used in this book. Much of the information presented here is standard knowledge among experts, but a consequence of this is that it is rarely discussed in current papers in the literature. A secondary goal of this chapter is to provide new users with a path through the extensive literature available and to point out potential difficulties and pitfalls in these calculations.

A fairly standard textbook on DFT is the one written by Parr and Yang.¹ The Chemist's Guide to DFT² is more readable and contains more practical information for running calculations, but both of these books focus on molecular systems. The standard texts in solid state physics are by Kittel³ and Ashcroft and Mermin.⁴ Both have their fine points, the former being more mathematically rigorous and the latter more readable. However, neither of these books is particularly easy to relate to chemistry. For this, one should consult the exceptionally clear writings of Roald Hoffman,^{5;6} and follow these with the work of Nørskov and coworkers.^{7;8}

In this chapter, only the elements of DFT that are relevant to this work will be discussed. An excellent review on other implementations of DFT can be found in Reference⁹, and details on the various algorithms used in DFT codes can be found in Refs.^{10;11}.

One of the most useful sources of information has been the dissertations of other students, perhaps because the difficulties they faced in learning the material are still fresh in their minds. Thomas Bligaard, a coauthor of Dacapo, wrote a particularly relevant thesis on exchange/correlation functionals¹² and a dissertation illustrating the use of DFT to design new alloys with desirable thermal and mechanical properties.¹³ The Ph.D. thesis of Ari Seitsonen

contains several useful appendices on k-point setups, and convergence tests of calculations, in addition to a thorough description of DFT and analysis of calculation output.¹⁴ Finally, another excellent overview of DFT and its applications to bimetallic alloy phase diagrams and surface reactivity is presented in the PhD thesis of Robin Hirschl.¹⁵

2.1 Background

In 1926, Erwin Schrödinger published the first accounts of his now famous wave equation.¹⁶ He later shared the Nobel prize with Paul A. M. Dirac in 1933 for this discovery. Schrödinger’s wave function seemed extremely promising, as it contains all of the information available about a system. Unfortunately, most practical systems of interest consist of many interacting electrons, and the effort required to find solutions to Schrödinger’s equation increases exponentially with the number of electrons, limiting this approach to systems with a small number of relevant electrons, $N \lesssim O(10)$.¹⁷ Even if this rough estimate is off by an order of magnitude, a system with 100 electrons is still very small, for example, two Ru atoms if all the electrons are counted, or perhaps ten Pt atoms if only the valence electrons are counted. Thus, the wave function method, which has been extremely successful in studying the properties of small molecules, is unsuitable for studies of large, extended solids. Interestingly, this difficulty was recognized by Dirac as early as 1929, when he wrote “The underlying physical laws necessary for the mathematical theory of a large part of physics and the whole of chemistry are thus completely known, and the difficulty is only that the application of these laws leads to equations much too complicated to be soluble.”¹⁸

In 1964, Hohenberg and Kohn showed that the ground state total energy of a system of interacting electrons is a unique functional of the electron density.¹⁹ By definition, a function returns a number when given a number. For example, in $f(x) = x^2$, $f(x)$ is the function, and it equals four when $x = 2$. A functional returns a number when given a function. Thus, in $g(f(x)) = \int_0^\pi f(x)dx$, $g(f(x))$ is the functional, and it is equal to two when $f(x) = \sin(x)$. Hohenberg and Kohn further identified a variational principle that appeared to reduce the problem of finding the ground state energy of an electron gas in an external potential (i.e., in the presence of ion cores) to that of the minimization of a functional of the three-dimensional density function. Unfortunately, the definition of the functional involved a set of $3N$ -dimensional trial wave functions.

In 1965, Kohn and Sham made a significant breakthrough when they showed that the problem of many interacting electrons in an external potential can be mapped exactly to a set of noninteracting electrons in an effective external potential.²⁰ This led to a set of self-consistent, single particle equations known as the Kohn-Sham (KS) equations:

$$\left(-\frac{1}{2}\nabla^2 + v_{eff}(\mathbf{r}) - \epsilon_j\right)\varphi_j(\mathbf{r}) = 0, \quad (1)$$

with

$$v_{eff}(\mathbf{r}) = v(\mathbf{r}) + \int \frac{n(\mathbf{r}')}{|\mathbf{r} - \mathbf{r}'|} d\mathbf{r}' + v_{xc}(\mathbf{r}), \quad (2)$$

where $v(\mathbf{r})$ is the external potential and $v_{xc}(\mathbf{r})$ is the exchange-correlation potential, which depends on the entire density function. Thus, the density needs to be known in order to define the effective potential so that Eq. (1) can be solved. $\varphi_j(\mathbf{r})$ corresponds to the j^{th} KS orbital of energy ϵ_j .

The ground state density is given by:

$$n(\mathbf{r}) = \sum_{j=1}^N |\varphi_j(\mathbf{r})|^2 \quad (3)$$

To solve Eq. (1) then, an initial guess is used for $\varphi_j(r)$ which is used to generate Eq. (3), which is subsequently used in Eq. (2). This equation is then solved for $\varphi_j(\mathbf{r})$ iteratively until the $\varphi_j(\mathbf{r})$ that result from the solution are the same as the $\varphi_j(\mathbf{r})$ that are used to define the equations, that is, the solutions are self-consistent. Finally, the ground state energy is given by:

$$E = \sum_j \epsilon_j + E_{xc}[n(\mathbf{r})] - \int v_{xc}(\mathbf{r})n(\mathbf{r})d\mathbf{r} - \frac{1}{2} \int \frac{n(\mathbf{r})n(\mathbf{r}')}{|\mathbf{r} - \mathbf{r}'|}d\mathbf{r}'d\mathbf{r}, \quad (4)$$

where $E_{xc}[n(\mathbf{r})]$ is the exchange-correlation energy functional. Walter Kohn shared the Nobel prize in Chemistry in 1998 for this work.¹⁷ The other half of the prize went to John Pople for his efforts in wave function based quantum mechanical methods.²¹ Provided the exchange-correlation energy functional is known, Eq. (4) is exact. However, the exact form of the exchange-correlation energy functional is not known, thus approximations for this functional must be used.

2.2 Exchange correlation functionals

The two main types of exchange/correlation functionals used in DFT are the local density approximation (LDA) and the generalized gradient approximation (GGA). In the LDA, the exchange-correlation functional is defined for an electron in a uniform electron gas of density n .²⁰ It is obviously exact for a uniform electron gas, and is anticipated to be valid for slowly varying densities. In molecules and solids, however, the density tends to vary substantially in space. Despite this, the LDA has been very successfully used in many systems. It tends to predict overbonding in both molecular and solid systems,²² and it tends to make semiconductor systems too metallic (the band gap problem).²³

The generalized gradient approximation includes corrections for gradients in the electron density, and is often implemented as a corrective function of the LDA. The form of this corrective function, or “exchange enhancement” function determines which functional it is, e.g. PBE, RPBE, revPBE, etc.²⁴ In this book the PBE GGA functional is used the most. N{Ø}rskov and coworkers have found that the RPBE functional gives superior chemisorption energies for atomic and molecular bonding to surfaces, but that it gives worse bulk properties, such as lattice constants compared to experimental data.²⁴

Finally, there are increasingly new types of functionals in the literature. The so-called hybrid functionals, such as B3LYP, are more popular with gaussian basis sets (e.g. in Gaussian), but they are presently inefficient with planewave basis sets. None of these other types of functionals were used in this work. For more details see Chapter 6 in Ref.² and Thomas Bligaard’s thesis on exchange and correlation functionals.¹²

2.3 Basis sets

Briefly, VASP utilizes planewaves as the basis set to expand the Kohn-Sham orbitals. In a periodic solid, one can use Bloch’s theorem to show that the wave function for an electron can

be expressed as the product of a planewave and a function with the periodicity of the lattice⁴ Ch. 8:

$$\psi_{n\mathbf{k}}(\mathbf{r}) = \exp(i\mathbf{k} \cdot \mathbf{r})u_{n\mathbf{k}}(\mathbf{r}) \quad (5)$$

where \mathbf{r} is a position vector, and \mathbf{k} is a so-called wave vector that will only have certain allowed values defined by the size of the unit cell. Bloch's theorem sets the stage for using planewaves as a basis set, because it suggests a planewave character of the wave function. If the periodic function $u_{n\mathbf{k}}(\mathbf{r})$ is also expanded in terms of planewaves determined by wave vectors of the reciprocal lattice vectors, \mathbf{G} , then the wave function can be expressed completely in terms of a sum of planewaves:¹⁰

$$\psi_i(\mathbf{r}) = \sum_{\mathbf{G}} c_{i,\mathbf{k}+\mathbf{G}} \exp(i(\mathbf{k} + \mathbf{G}) \cdot \mathbf{r}). \quad (6)$$

where $c_{i,\mathbf{k}+\mathbf{G}}$ are now coefficients that can be varied to determine the lowest energy solution. This also converts Eq. (1) from an integral equation to a set of algebraic equations that can readily be solved using matrix algebra.

In aperiodic systems, such as systems with even one defect, or randomly ordered alloys, there is no periodic unit cell. Instead one must represent the portion of the system of interest in a supercell, which is then subjected to the periodic boundary conditions so that a planewave basis set can be used. It then becomes necessary to ensure the supercell is large enough to avoid interactions between the defects in neighboring supercells. The case of the randomly ordered alloy is virtually hopeless as the energy of different configurations will fluctuate statistically about an average value. These systems were not considered in this work, and for more detailed discussions the reader is referred to Ref.²⁵ Once a supercell is chosen, however, Bloch's theorem can be applied to the new artificially periodic system.

To get a perfect expansion, one needs an infinite number of planewaves. Luckily, the coefficients of the planewaves must go to zero for high energy planewaves, otherwise the energy of the wave function would go to infinity. This provides justification for truncating the planewave basis set above a cutoff energy. Careful testing of the effect of the cutoff energy on the total energy can be done to determine a suitable cutoff energy. The cutoff energy required to obtain a particular convergence precision is also element dependent, shown in Table 1. It can also vary with the "softness" of the pseudopotential. Thus, careful testing should be done to ensure the desired level of convergence of properties in different systems. Table 1 refers to convergence of total energies. These energies are rarely considered directly, it is usually differences in energy that are important. These tend to converge with the planewave cutoff energy much more quickly than total energies, due to cancellations of convergence errors. In this work, 350 eV was found to be suitable for the H adsorption calculations, but a cutoff energy of 450 eV was required for O adsorption calculations.

Table 1: Planewave cutoff energies (in eV) required for different convergence precisions for different elements.

Precision	Low	High
Mo	168	293
O	300	520
O _{sv}	1066	1847

Bloch’s theorem eliminates the need to calculate an infinite number of wave functions, because there are only a finite number of electrons in the unit (super) cell. However, there are still an infinite number of discrete \mathbf{k} points that must be considered, and the energy of the unit cell is calculated as an integral over these points. It turns out that wave functions at \mathbf{k} points that are close together are similar, thus an interpolation scheme can be used with a finite number of \mathbf{k} points. This also converts the integral used to determine the energy into a sum over the \mathbf{k} points, which are suitably weighted to account for the finite number of them. There will be errors in the total energy associated with the finite number of \mathbf{k} , but these can be reduced and tested for convergence by using higher \mathbf{k} -point densities. An excellent discussion of this for aperiodic systems can be found in Ref.²⁵.

The most common schemes for generating \mathbf{k} points are the Chadi-Cohen scheme,²⁶ and the Monkhorst-Pack scheme.²⁷ The use of these \mathbf{k} point setups amounts to an expansion of the periodic function in reciprocal space, which allows a straight-forward interpolation of the function between the points that is more accurate than with other \mathbf{k} point generation schemes.²⁷

2.4 Pseudopotentials

The core electrons of an atom are computationally expensive with planewave basis sets because they are highly localized. This means that a very large number of planewaves are required to expand their wave functions. Furthermore, the contributions of the core electrons to bonding compared to those of the valence electrons is usually negligible. In fact, the primary role of the core electron wave functions is to ensure proper orthogonality between the valence electrons and core states. Consequently, it is desirable to replace the atomic potential due to the core electrons with a pseudopotential that has the same effect on the valence electrons.²⁸ There are essentially two kinds of pseudopotentials, norm-conserving soft pseudopotentials²⁸ and Vanderbilt ultrasoft pseudopotentials.²⁹ In either case, the pseudopotential function is generated from an all-electron calculation of an atom in some reference state. In norm-conserving pseudopotentials, the charge enclosed in the pseudopotential region is the same as that enclosed by the same space in an all-electron calculation. In ultrasoft pseudopotentials, this requirement is relaxed and charge augmentation functions are used to make up the difference. As its name implies, this allows a “softer” pseudopotential to be generated, which means fewer planewaves are required to expand it.

The pseudopotentials are not unique, and calculated properties depend on them. However, there are standard methods for ensuring the quality and transferability (to different chemical environments) of the pseudopotentials.³⁰

TODO: PAW description

VASP provides a database of PAW potentials.^{31;32}

2.5 Fermi Temperature and band occupation numbers

At absolute zero, the occupancies of the bands of a system are well-defined step functions; all bands up to the Fermi level are occupied, and all bands above the Fermi level are unoccupied. There is a particular difficulty in the calculation of the electronic structures of metals compared to semiconductors and molecules. In molecules and semiconductors, there is a clear energy gap between the occupied states and unoccupied states. Thus, the occupancies are insensitive to changes in the energy that occur during the self-consistency cycles. In metals, however, the density of states is continuous at the Fermi level, and there are typically a substantial number of

states that are close in energy to the Fermi level. Consequently, small changes in the energy can dramatically change the occupation numbers, resulting in instabilities that make it difficult to converge to the occupation step function. A related problem is that the Brillouin zone integral (which in practice is performed as a sum over a finite number of \mathbf{k} points) that defines the band energy converges very slowly with the number of \mathbf{k} points due to the discontinuity in occupancies in a continuous distribution of states for metals.^{11;33} The difficulty arises because the temperature in most DFT calculations is at absolute zero. At higher temperatures, the DOS is smeared across the Fermi level, resulting in a continuous occupation function over the distribution of states. A finite-temperature version of DFT was developed,³⁴ which is the foundation on which one solution to this problem is based. In this solution, the step function is replaced by a smoothly varying function such as the Fermi-Dirac function at a small, but non-zero temperature.¹¹ The total energy is then extrapolated back to absolute zero.

2.6 Spin polarization and magnetism

There are two final points that need to be discussed about these calculations, spin polarization and dipole corrections. Spin polarization is important for systems that contain net spin. For example, iron, cobalt and nickel are magnetic because they have more electrons with spin “up” than spin “down” (or vice versa). Spin polarization must also be considered in atoms and molecules with unpaired electrons, such as hydrogen and oxygen atoms, oxygen molecules and radicals. For example, there are two spin configurations for an oxygen molecule, the singlet state with no unpaired electrons, and the triplet state with two unpaired electrons. The oxygen triplet state is lower in energy than the oxygen singlet state, and thus it corresponds to the ground state for an oxygen atom. A classically known problem involving spin polarization is the dissociation of a hydrogen molecule. In this case, the molecule starts with no net spin, but it dissociates into two atoms, each of which has an unpaired electron. See section 5.3.5 in Reference² for more details on this.

In VASP, spin polarization is not considered by default; it must be turned on, and an initial guess for the magnetic moment of each atom in the unit cell must be provided (typically about one Bohr-magneton per unpaired electron). For Fe, Co, and Ni, the experimental values are 2.22, 1.72, and 0.61 Bohr-magnetons, respectively³ and are usually good initial guesses. See Reference³⁰ for a very thorough discussion of the determination of the magnetic properties of these metals with DFT. For a hydrogen atom, an initial guess of 1.0 Bohr-magnetons (corresponding to one unpaired electron) is usually good. An oxygen atom has two unpaired electrons, thus an initial guess of 2.0 Bohr-magnetons should be used. The spin-polarized solution is sensitive to the initial guess, and typically converges to the closest solution. Thus, a magnetic initial guess usually must be provided to get a magnetic solution. Finally, unless an adsorbate is on a magnetic metal surface, spin polarization typically does not need to be considered, although the gas-phase reference state calculation may need to be done with spin-polarization.

The downside of including spin polarization is that it essentially doubles the calculation time.

3 Molecules

In this chapter we consider how to construct models of molecules, how to manipulate them, and how to calculate many properties of molecules. For a nice comparison of VASP and Gaussian see³⁹.

3.1 Defining and visualizing molecules

We start by learning how to define a molecule and visualize it. We will begin with defining molecules from scratch, then reading molecules from data files, and finally using some built-in databases in `ase`.

3.1.1 From scratch

When there is no data file for the molecule you want, or no database to get it from, you have to define your atoms geometry by hand. Here is how that is done for a CO molecule (Figure 1). We must define the type and position of each atom, and the unit cell the atoms are in.

```
1 from ase import Atoms, Atom
2 from ase.io import write
3
4 # define an Atoms object
5 atoms = Atoms([Atom('C',[0., 0.,0.]),
6               Atom('O',[1.1,0.,0.]),
7               cell=(10,10,10))
8
9 print 'V = {0:1.0f} Angstrom^3'.format(atoms.get_volume())
10
11 write('images/simple-cubic-cell.png',atoms,show_unit_cell=2)
```

V = 1000 Ang³

Figure 1: Image of a CO molecule with the C at the origin.

There are two inconvenient features of the simple cubic cell:

1. Since the CO molecule is at the corner, its electron density is spread over the 8 corners of the box, which is not convenient for visualization later (see [Visualizing electron density](#)).
2. Due to the geometry of the cube, you need fairly large cubes to make sure the electron density of the molecule does not overlap with that of its images. Electron-electron interactions are repulsive, and the overlap makes the energy increase significantly. Here, the CO molecule has 6 images due to periodic boundary conditions that are 10 Å away. The volume of the unit cell is 1000 Å³.

The first problem is easily solved by centering the atoms in the unit cell. The second problem can be solved by using a face-centered cubic lattice, which is the lattice with the closest packing. We show the results of the centering in Figure 2, where we have guessed values for b until the CO molecules are on average 10 Å apart. Note the final volume is only about 715 Å³, which is smaller than the cube. This will result in less computational time to compute properties.

```

1 from ase import Atoms, Atom
2 from ase.io import write
3
4 b = 7.1
5 atoms = Atoms([Atom('C', [0., 0., 0.]),
```

```

6         Atom('O',[1.1,0.,0.]),
7         cell=[[b, b, 0.],
8              [b, 0., b],
9              [0., b, b]])
10 print 'V = {0:1.0f} Ang^3'.format(atoms.get_volume())
11
12 atoms.center() #translate atoms to center of unit cell
13 write('images/fcc-cell.png', atoms, show_unit_cell=2)

```

V = 716 Ang³

Figure 2: CO in a face-centered cubic unit cell.

At this point you might ask, “How do you know the distance to the neighboring image?” The **ag** viewer lets you compute this graphically, but we can use code to determine this too. All we have to do is figure out the length of each lattice vector, because these are what separate the atoms in the images. We use the **numpy** module to compute the distance of a vector as the square root of the sum of squared elements.

```

1 from ase import Atoms, Atom
2 import numpy as np
3
4 b = 7.1
5 atoms = Atoms([Atom('C',[0., 0.,0.]),
6               Atom('O',[1.1,0.,0.]),

```

```

7         cell=[[b, b, 0.],
8               [b, 0., b],
9               [0., b, b]])
10
11 # get unit cell vectors and their lengths
12 (a1, a2, a3) = atoms.get_cell()
13 print '|a1| = {0:1.2f} Ang'.format(np.sum(a1**2)**0.5)
14 print '|a2| = {0:1.2f} Ang'.format(np.linalg.norm(a2))
15 print '|a3| = {0:1.2f} Ang'.format(np.sum(a3**2)**0.5)

```

```

|a1| = 10.04 Ang
|a2| = 10.04 Ang
|a3| = 10.04 Ang

```

3.1.2 Reading other data formats into a calculation

`ase.io.read` supports many different file formats:

Known formats:

format	short name
GPaw restart-file	gpw
Dacapo netCDF output file	dacapo
Old ASE netCDF trajectory	nc
Virtual Nano Lab file	vnl
ASE pickle trajectory	traj
ASE bundle trajectory	bundle
GPaw text output	gpaw-text
CUBE file	cube
XCrySDen Structure File	xsf
Dacapo text output	dacapo-text
XYZ-file	xyz
VASP POSCAR/CONTCAR file	vasp
VASP OUTCAR file	vasp_out
SIESTA STRUCT file	struct_out
ABINIT input file	abinit
V_Sim ascii file	v_sim
Protein Data Bank	pdb
CIF-file	cif
FHI-aims geometry file	aims
FHI-aims output file	aims_out
VTK XML Image Data	vti
VTK XML Structured Grid	vti
VTK XML Unstructured Grid	vtu
TURBOMOLE coord file	tmol
TURBOMOLE gradient file	tmol-gradient
exciting input	exi

AtomEye configuration	cfg
WIEN2k structure file	struct
DftbPlus input file	dftb
CASTEP geom file	cell
CASTEP output file	castep
CASTEP trajectory file	geom
ETSF format	etsf.nc
DFTBPlus GEN format	gen
CMR db/cmr-file	db
CMR db/cmr-file	cmr
LAMMPS dump file	lammps
Gromacs coordinates	gro
=====	=====

You can read XYZ file format to create `ase.Atoms` objects. Here is what an XYZ file format might look like:

14

C	0.0000000000000000	0.0000000000000000	0.3769490000000000

H	-1.2760550000000000	-1.7591980000000000	0.2612970000000000
H	-2.1615370000000000	-0.2254980000000000	0.2612970000000000

The first line is the number of atoms in the file. The second line is often a comment. What follows is one line per atom with the symbol and Cartesian coordinates in Å. Note that the XYZ format does not have unit cell information in it, so you will have to figure out a way to provide it. In this example, we center the atoms in a box with vacuum on all sides (Figure 3).

```

1 from ase.io import read,write
2 import numpy as np
3
4 atoms = read('molecules/isobutane.xyz')
5 atoms.center(vacuum=5)
6 write('images/isobutane-xyz.png', atoms, show_unit_cell=2)

```

None

Figure 3: An isobutane molecule read in from an XYZ formatted data file.

3.1.3 Predefined molecules

`ase` defines a number of molecular geometries in the `ase.data.molecules` database. For example, the database includes the molecules in the G2/97 database.⁴⁰ This database contains a broad set of atoms and molecules for which good experimental data exists, making them useful for benchmarking studies. See [this site](#) for the original files.

The coordinates for the atoms in the database are `MP2(full)/6-31G(d)` optimized geometries. Here is a list of all the species available in `ase.data.g2`. You may be interested in reading about some of the other databases in `ase.data` too.

```

1 from ase.data import g2
2 keys = g2.data.keys()
3 # print in 3 columns
4 for i in range(len(keys)/3):
5     print '{0:25s}{1:25s}{2:25s}'.format(*tuple(keys[i*3:i*3+3]))

```

CH3CN

Some other databases include the `ase.data.s22` for weakly interacting dimers and complexes, and `ase.data.extra_molecules` which has a few extras like biphenyl and C60.

Here is an example of getting the geometry of an acetonitrile molecule and writing an image to a file. Note that the default unit cell is a $1\text{\AA} \times 1\text{\AA} \times 1\text{\AA}$ cubic cell. That is too small to use if your calculator uses periodic boundary conditions. We center the atoms in the unit cell and add vacuum on each side. We will add 6 \AA of vacuum on each side. In the write command we use the option `show_unit_cell=2` to draw the unit cell boundaries. See Figure 4.

```
1 from ase.data.molecules import molecule
2 from ase.io import write
3
4 atoms = molecule('CH3CN')
5
6 atoms.center(vacuum=6)
7 print 'unit cell'
8 print '-----'
9 print atoms.get_cell()
10
11 write('images/ch3cn.png', atoms, show_unit_cell=2)
```

```
unit cell
-----
[[ 13.775328  0.          0.          ]
 [  0.         13.537479  0.          ]
 [  0.          0.         15.014576]]
```

Figure 4: A CH_3CN molecule in a box.

It is possible to rotate the atoms with `ase.io.write` if you wanted to see pictures from another angle. In the next example we rotate 45 degrees about the x -axis, then 45 degrees about the y -axis. Note that this only affects the image, not the actual coordinates. See [Figure 5](#)

```

1 from ase.data.molecules import molecule
2 from ase.io import write
3
4 atoms = molecule('CH3CN')
5
6 atoms.center(vacuum=6)
7 print 'unit cell'
8 print '-----'
9 print atoms.get_cell()
10
11 write('images/ch3cn-rotated.png', atoms,
12       show_unit_cell=2, rotation='45x,45y,0z')
```

```

unit cell
-----
[[ 13.775328   0.         0.         ]
 [  0.         13.537479   0.         ]
 [  0.         0.         15.014576]]
```

Figure 5: The rotated version of CH₃CN.

If you actually want to rotate the coordinates, there is a nice way to do that too, with the `ase.Atoms.rotate` method. Actually there are some subtleties in rotation. One rotates the molecule an angle (in radians) around a vector, but you have to choose whether the center of mass should be fixed or not. You also must decide whether or not the unit cell should be rotated. In the next example you can see the coordinates have changed due to the rotations. Note that the write function uses the rotation angle in degrees, while the rotate function uses radians.

```

1  from ase.data.molecules import molecule
2  from ase.io import write
3  from numpy import pi
4
5  atoms = molecule('CH3CN')
6  atoms.center(vacuum=6)
7  p1 = atoms.get_positions()
8
9  atoms.rotate('x', pi/4, center='COM', rotate_cell=False)
10 atoms.rotate('y', pi/4, center='COM', rotate_cell=False)
11
12 write('images/ch3cn-rotated-2.png', atoms, show_unit_cell=2)
13 print 'difference in positions after rotating'
14 print 'atom      difference vector'
15 print '-----'
16 p2 = atoms.get_positions()
17
18 diff = p2 - p1
19 for i, d in enumerate(diff):
20     print '{0} {1}'.format(i, d)

```

difference in positions after rotating

atom	difference vector
0	[-0.65009456 0.91937255 0.65009456]
1	[0.08030744 -0.11357187 -0.08030744]
2	[0.66947344 -0.94677841 -0.66947344]
3	[-0.32532156 0.88463727 1.35030756]
4	[-1.35405183 1.33495444 -0.04610517]
5	[-0.8340703 1.33495444 1.2092413]

Figure 6: Rotated CH_3CN molecule

Note in this last case the unit cell is oriented differently than the previous example, since we chose not to rotate the unit cell.

3.1.4 Combining Atoms objects

It is frequently useful to combine two `Atoms` objects, e.g. for computing reaction barriers, or other types of interactions. In `ase`, we simply add two `Atoms` objects together. Here is an example of getting an ammonia and oxygen molecule in the same unit cell. See Figure 7. We set the `Atoms` about three Å apart using the `ase.Atoms.translate` function.

```

1  from ase.data.molecules import molecule
2  from ase.io import write
3
4  atoms1 = molecule('NH3')
5
6  atoms2 = molecule('O2')
7  atoms2.translate([3, 0, 0])
8
9  bothatoms = atoms1 + atoms2
10 bothatoms.center(5)
11
12 write('images/bothatoms.png', bothatoms, show_unit_cell=2, rotation='90x')
```

Figure 7: Image featuring ammonia and oxygen molecule in one unit cell.

3.2 Simple properties

Simple properties do not require a DFT calculation. They are typically only functions of the atom types and geometries.

3.2.1 Getting cartesian positions

If you want the (x, y, z) coordinates of the atoms, use the `ase.Atoms.get_positions`. If you are interested in the fractional coordinates, use `ase.Atoms.get_scaled_positions`.

```

1  from ase.data.molecules import molecule
2  from ase.io import write
3
4  atoms = molecule('C6H6') # benzene
5
6  # access properties on each atom
7  print ' # sym  p_x    p_y    p_z'
8  print '-----'
9  for i, atom in enumerate(atoms):
10     print '{0:3d}{1:^4s}{2:-8.2f}{3:-8.2f}{4:-8.2f}'.format(i,
11                                                             atom.symbol,
12                                                             atom.x,
13                                                             atom.y,
14                                                             atom.z)
15
16  # get all properties in arrays
17  sym = atoms.get_chemical_symbols()
18  pos = atoms.get_positions()
19  num = atoms.get_atomic_numbers()
20
21  atom_indices = range(len(atoms))

```

```

22
23 print
24 print ' # sym    at#    p_x    p_y    p_z'
25 print '-----',
26 for i, s, n, p in zip(atom_indices, sym, num, pos):
27     px, py, pz = p
28     print '{0:3d}{1:>3s}{2:8d}{3:-8.2f}{4:-8.2f}{5:-8.2f}'.format(i, s, n,
29                                                                    px, py, pz)

```

#	sym	p_x	p_y	p_z
0	C	0.00	1.40	0.00
1	C	1.21	0.70	0.00
2	C	1.21	-0.70	0.00
3	C	0.00	-1.40	0.00
4	C	-1.21	-0.70	0.00
5	C	-1.21	0.70	0.00
6	H	0.00	2.48	0.00
7	H	2.15	1.24	0.00
8	H	2.15	-1.24	0.00
9	H	0.00	-2.48	0.00
10	H	-2.15	-1.24	0.00
11	H	-2.15	1.24	0.00

#	sym	at#	p_x	p_y	p_z
0	C	6	0.00	1.40	0.00
1	C	6	1.21	0.70	0.00
2	C	6	1.21	-0.70	0.00
3	C	6	0.00	-1.40	0.00
4	C	6	-1.21	-0.70	0.00
5	C	6	-1.21	0.70	0.00
6	H	1	0.00	2.48	0.00
7	H	1	2.15	1.24	0.00
8	H	1	2.15	-1.24	0.00
9	H	1	0.00	-2.48	0.00
10	H	1	-2.15	-1.24	0.00
11	H	1	-2.15	1.24	0.00

3.2.2 Molecular weight and molecular formula

We can quickly compute the molecular weight of a molecule with this recipe. We use `ase.Atoms.get_masses` to get an array of the atomic masses of each atom in the `Atoms` object, and then just sum them up.

```

1 from ase.data.molecules import molecule
2
3 atoms = molecule('C6H6')
4 masses = atoms.get_masses()
5

```

```

6 molecular_weight = masses.sum()
7 molecular_formula = atoms.get_chemical_symbols(reduce=True)
8 print 'The molecular weight of {0} is {1:1.2f} gm/mol'.format(molecular_formula,
9                                                                molecular_weight)

```

The molecular weight of C6H6 is 78.11

Note that the argument `reduce=True` for `ase.Atoms.get_chemical_symbols` collects all the symbols to provide a molecular formula.

3.2.3 Center of mass

The center of mass (COM) is defined as:

$$\text{COM} = \frac{\sum m_i r_i}{\sum m_i}$$

The center of mass is essentially the average position of the atoms, weighted by the mass of each atom. Here is an example of getting the center of mass from an `Atoms` object using `ase.Atoms.get_center_of_mass`.

```

1 from ase.structure import molecule
2 from ase.io import write
3 import numpy as np
4
5 # ammonia
6 atoms = molecule('NH3')
7
8 print 'COM1 = {0}'.format(atoms.get_center_of_mass()) # cartesian coordinates
9
10 # compute the center of mass by hand
11 pos = atoms.positions
12 masses = atoms.get_masses()
13
14 COM = np.array([0., 0., 0.])
15 for m,p in zip(masses, pos):
16     COM += m*p
17 COM /= masses.sum()
18
19 print 'COM2 = {0}'.format(COM)
20
21 # one-line linear algebra definition of COM
22 print 'COM3 = {0}'.format(np.dot(masses, pos)/np.sum(masses))

```

```

COM1 = [ 0.00000000e+00  5.91843349e-08  4.75457009e-02]
COM2 = [ 0.00000000e+00  5.91843349e-08  4.75457009e-02]
COM3 = [ 0.00000000e+00  5.91843349e-08  4.75457009e-02]

```

You can see that these centers of mass, which are calculated by different methods, are the same.

3.2.4 Moments of inertia

The [moment of inertia](#) is a measure of resistance to changes in rotation. It is defined by $I = \sum_{i=1}^N m_i r_i^2$ where r_i is the distance to an axis of rotation. There are typically three moments of inertia, although some may be zero depending on symmetry, and others may be degenerate. There is a convenient function to get the moments of inertia: `ase.Atoms.get_moments_of_inertia`. Here are several examples of molecules with different types of symmetry:

```

1  from ase.structure import molecule
2
3  print 'linear rotors: I = [0 Ia Ia]'
4  atoms = molecule('CO2')
5  print ' CO2 moments of inertia: ',atoms.get_moments_of_inertia()
6  print
7
8  print 'symmetric rotors (Ia = Ib) < Ic'
9  atoms = molecule('NH3')
10 print ' NH3 moments of inertia: ',atoms.get_moments_of_inertia()
11
12 atoms = molecule('C6H6')
13 print ' C6H6 moments of inertia: ',atoms.get_moments_of_inertia()
14 print
15
16 print 'symmetric rotors Ia < (Ib = Ic)'
17 atoms = molecule('CH3Cl')
18 print 'CH3Cl moments of inertia: ',atoms.get_moments_of_inertia()
19 print
20
21 print 'spherical rotors Ia = Ib = Ic'
22 atoms = molecule('CH4')
23 print ' CH4 moments of inertia: ',atoms.get_moments_of_inertia()
24 print
25
26 print 'unsymmetric rotors Ia != Ib != Ic'
27 atoms = molecule('C3H7Cl')
28 print ' C3H7Cl moments of inertia: ',atoms.get_moments_of_inertia()

```

linear rotors: I = [0 Ia Ia]

CO2 moments of inertia: [0. 44.45384271 44.45384271]

symmetric rotors (Ia = Ib) < Ic

NH3 moments of inertia: [1.71012426 1.71012548 2.67031768]

C6H6 moments of inertia: [88.77914641 88.77916799 177.5583144]

symmetric rotors Ia < (Ib = Ic)

CH3Cl moments of inertia: [3.20372189 37.97009644 37.97009837]

spherical rotors Ia = Ib = Ic

CH4 moments of inertia: [3.19145621 3.19145621 3.19145621]

unsymmetric rotors Ia != Ib != Ic

C3H7Cl moments of inertia: [19.41351508 213.18961963 223.16255537]

If you want to know the principle axes of rotation, we simply pass `vectors=True` to the function, and it returns the moments of inertia and the principle axes.

```

1  from ase.structure import molecule
2  import numpy as np
3
4  atoms = molecule('CH3Cl')
5  moments, axes = atoms.get_moments_of_inertia(vectors=True)
6  print 'Moments = {0}'.format(moments)
7  print 'axes = {0}'.format(axes)

```

```

Moments = [ 3.20372189  37.97009644  37.97009837]
axes = [[ 0.  0.  1.]
        [ 0.  1.  0.]
        [ 1.  0.  0.]]

```

This shows the first moment is about the z-axis, the second moment is about the y-axis, and the third moment is about the x-axis.

3.2.5 Computing bond lengths and angles

A typical question we might ask is, “What is the structure of a molecule?” In other words, what are the bond lengths, angles between bonds, and similar properties. The `Atoms` object contains an `ase.Atoms.get_distance` method to make this easy. To calculate the distance between two atoms, you have to specify their indices, remembering that the index starts at 0.

```

1 from ase.structure import molecule
2 from ase.io import write
3
4 # ammonia
5 atoms = molecule('NH3')
6
7 print 'atom symbol'
8 print '======'
9 for i, atom in enumerate(atoms):
10     print '{0:2d} {1:3s}'.format(i, atom.symbol)
11
12 # N-H bond length
13 s = 'The N-H distance is {0:1.3f} angstroms'
14 print s.format(atoms.get_distance(0,1))

```

```

atom symbol
=====

```

```

0  N
1  H
2  H
3  H

```

```
The N-H distance is 1.017 angstroms
```

Bond angles are a little trickier. If we had vectors describing the directions between two atoms, we could use some simple trigonometry to compute the angle between the vectors: $\vec{a} \cdot \vec{b} = |\vec{a}||\vec{b}|\cos(\theta)$. So we can calculate the angle as $\theta = \arccos\left(\frac{\vec{a} \cdot \vec{b}}{|\vec{a}||\vec{b}|}\right)$, we just have to define our two vectors \vec{a} and \vec{b} . We compute these vectors as the difference in positions of two atoms. For example, here we compute the angle H-N-H in an ammonia molecule. This is the angle between N-H₁ and N-H₂. In the next example, we utilize functions in `numpy` to perform the calculations, specifically the `numpy.arccos` function, the `numpy.dot` function, and `numpy.linalg.norm` functions.

```

1 from ase.structure import molecule
2 from ase.io import write
3
4 # ammonia

```

```

5  atoms = molecule('NH3')
6
7  print 'atom symbol'
8  print '======'
9  for i, atom in enumerate(atoms):
10     print '{0:2d} {1:3s}'.format(i,atom.symbol)
11
12  a = atoms.positions[0] - atoms.positions[1]
13  b = atoms.positions[0] - atoms.positions[2]
14
15  from numpy import arccos, dot, pi
16  from numpy.linalg import norm
17
18  theta_rad = arccos(dot(a,b)/(norm(a)*norm(b))) # in radians
19
20  print 'theta = {0:1.1f} degrees'.format(theta_rad*180./pi)

```

```

atom symbol
=====
0    N
1    H
2    H
3    H
theta = 106.3 degrees

```

Figure 8: Schematic of the vectors defining the H-N-H angle.

Alternatively you could use `ase.Atoms.get_angle`. Note we want the angle between atoms with indices [1, 0, 2] to get the H-N-H angle.

```

1 from ase.data.molecules import molecule
2 from numpy import pi
3 # ammonia
4 atoms = molecule('NH3')
5
6 print 'theta = {0} degrees'.format(atoms.get_angle([1,0,2])*180./pi)

```

theta = 106.334624232 degrees

Dihedral angles There is support in ase for computing [dihedral angles](#). Let us illustrate that for ethane. We will compute the dihedral angle between atoms 5, 1, 0, and 4. That is a H-C-C-H dihedral angle, and one can visually see (although not here) that these atoms have a dihedral angle of 60° (Figure 9).

```

1 # calculate an ethane dihedral angle
2 from ase.structure import molecule
3 import numpy as np
4
5 atoms = molecule('C2H6')
6
7 print 'atom symbol'
8 print '======'
9 for i, atom in enumerate(atoms):
10     print '{0:2d} {1:3s}'.format(i,atom.symbol)
11
12 da = atoms.get_dihedral([5,1,0,4])*180./np.pi
13 print 'dihedral angle = {0:1.2f} degrees'.format(da)

```

atom symbol

=====

```

0  C
1  C
2  H
3  H
4  H
5  H
6  H
7  H

```

dihedral angle = 60.00 degrees

Figure 9: Schematic of the calculated ethane dihedral angle.

In this section we cover properties that require simple calculations, but not DFT calculations, to compute.

3.3 Simple properties that require computations

3.3.1 Energy and forces

Two of the most important quantities we are interested in are the total energy and the forces on the atoms. To get these quantities, we have to define a calculator and attach it to an `ase.Atoms` object so that `ase` knows how to get the data. After defining the calculator a DFT calculation must be run.

Here is an example of getting the energy and forces from a CO molecule. The forces in this case are very high, indicating that this geometry is not close to the ground state geometry. Note that the forces are only along the x -axis, which is along the molecular axis. We will see how to minimize this force in [Manual determination](#) and [Automatic geometry optimization with VASP](#).

Note:

This is your first DFT calculation in the book! see [ISMear](#), [SIGMA](#), [NBANDS](#), and [ENCUT](#) to learn more about these VASP keywords.

```
1 from ase import Atoms, Atom
2 from jasp import *
3 import numpy as np
4 np.set_printoptions(precision=3, suppress=True)
5
6 co = Atoms([Atom('C', [0, 0, 0]),
7             Atom('O', [1.2, 0, 0])],
8            cell=(6., 6., 6.))
9
10 with jasp('molecules/simple-co', #output dir
11          xc='PBE', # the exchange-correlation functional
12          nbands=6, # number of bands
13          encut=350, # planewave cutoff
14          ismear=1, # Methfessel-Paxton smearing
15          sigma=0.01, # very small smearing factor for a molecule
16          atoms=co) as calc:
17     print 'energy = {0} eV'.format(co.get_potential_energy())
18     print co.get_forces()
```

```
energy = -14.687906 eV
[[ 5.095  0.    0.   ]
 [-5.095  0.    0.   ]]
```

Convergence with unit cell size There are a number of parameters that affect the energy and forces including the calculation parameters and the unit cell. We will first consider the effect of the unit cell on the total energy and forces. The reason that the unit cell affects the total energy is that it can change the distribution of electrons in the molecule.

```
1 from jasp import *
2 from ase import Atoms, Atom
3 import numpy as np
4 np.set_printoptions(precision=3, suppress=True)
5
6 atoms = Atoms([Atom('C', [0, 0, 0]),
7                 Atom('O', [1.2, 0, 0])])
8
9 L = [4, 5, 6, 8, 10]
```

```

10
11 volumes, energies = [], []
12 for a in L:
13     atoms.set_cell([a,a,a], scale_atoms=False)
14     atoms.center()
15     with jasp('molecules/co-L-{}'.format(a),
16             encut=350,
17             xc='PBE',
18             atoms=atoms) as calc:
19         try:
20             energies.append(atoms.get_potential_energy())
21         except (VaspSubmitted, VaspQueued):
22             pass
23 import matplotlib.pyplot as plt
24 plt.plot(L, energies, 'bo')
25 plt.xlabel('Unit cell length (Å)')
26 plt.ylabel('Total energy (eV)')
27 plt.savefig('images/co-e-v.png')
28 plt.show()

```

None

Figure 10: Total energy of a CO molecule as a function of the unit cell length.

Here there are evidently attractive interactions between the CO molecules which lower the total energy for small box sizes. We have to decide what an appropriate volume for our calculation is, and the choice depends on the goal. We may wish to know the total energy of a molecule that is not interacting with any other molecules, e.g. in the ideal gas limit. In that case we need a large unit cell so the electron density from the molecule does not go outside the unit cell where it would overlap with neighboring images.

Let us consider what the pressure in the unit cell is. In the ideal gas limit we have $PV = nRT$, which gives a pressure of zero at absolute zero. At non-zero temperatures, we have

$P = n/VRT$. Let us consider some examples. In atomic units we use k_B instead of R , and it has a value of

```

1  from ase.units import kB, Pascal
2  import numpy as np
3  import matplotlib.pyplot as plt
4
5  atm = 101325 * Pascal
6
7  L = np.linspace(4,10)
8  V = L**3
9
10 n = 1 # one atom per unit cell
11
12 for T in [298, 600, 1000]:
13     P = n/V*kB*T / atm # convert to atmospheres
14
15     plt.plot(V, P, label='{0}K'.format(T))
16
17 plt.xlabel('Unit cell volume ($\AA^3$)')
18 plt.ylabel('Pressure (atm)')
19 plt.legend(loc='best')
20 plt.savefig('images/ideal-gas-pressure.png')
21 plt.show()

```

None

Figure 11: Ideal gas pressure dependence on temperature and unit cell volume.

Convergence of ENCUT The total energy and forces also depend on the computational parameters, notably [ENCUT](#).

```

1  from ase import Atoms, Atom
2  from jasp import *
3  import numpy as np
4  np.set_printoptions(precision=3, suppress=True)
5
6  atoms = Atoms([Atom('C',[0, 0, 0]),
7                Atom('O',[1.2, 0, 0])])
8
9  ENCUTS = [250, 300, 350, 400, 450, 500]
10
11  energies = []
12  for en in ENCUTS:
13      atoms.set_cell([a,a,a], scale_atoms=False)
14      atoms.center()
15
16      with jasp('molecules/co-en-{0}'.format(en),
17              encut=en,
18              xc='PBE',
19              atoms=atoms) as calc:
20          try:
21              energies.append(atoms.get_potential_energy())
22          except (VaspSubmitted, VaspQueued):
23              pass
24  import matplotlib.pyplot as plt
25  plt.plot(ENCUTS, energies, 'bo')
26  plt.xlabel('ENCUT (eV)')
27  plt.ylabel('Total energy (eV)')
28  plt.savefig('images/co-encut-v.png')

```

Keep in mind that we are generally interested in differences in total energy, and the differences tend to converge faster than a single total energy. Also it is important to note that it is usually a single element that determines the rate of convergence.

3.3.2 The density of states (DOS)

The density of states (DOS) gives you the number of electronic states (i.e. orbitals) that have a particular energy. We can get this information from the last calculation we just ran without having to run another DFT calculation.

Warning:

One way that `jasp` is unintuitive is that whenever you are “inside” (indented) a `with` statement, the current working directory may be different than where your script started. In this example that can lead to your figure not being saved where you expect it!

```

1  from jasp import *
2  from ase.dft.dos import DOS
3  import matplotlib.pyplot as plt
4
5  with jasp('molecules/simple-co') as calc: # we already ran this!
6      dos = DOS(calc)
7      plt.plot(dos.get_energies(), dos.get_dos())
8      plt.xlabel('Energy - $E_f$ (eV)')
9      plt.ylabel('DOS')
10
11  # make sure you save the figure outside the with statement, or provide
12  # the correct relative or absolute path to where you want it.

Figure 12: Density of states for a CO molecule.

3.3.3 Atom-projected density of states on molecules

Let us consider which states in the density of states belong to which atoms in a molecule. This can only be a qualitative consideration because the orbitals on the atoms often hybridize to form molecular orbitals, e.g. in methane the s and p orbitals can form what we call sp_3 orbitals. We can compute atom-projected density of states in VASP, which is done by projecting the wave function onto localized atomic orbitals. Here is an example. We will consider the CO molecule. To get atom-projected density of states, we must set [RWIGS](#) for each atom. This parameter defines the radius of the sphere around the atom which cuts off the projection. The total density of states and projected density of states information comes from the DOSCAR file.

Note that unlike the DOS, here we must run another calculation because we did not specify the atom-projected keywords above. Our strategy is to get the atoms from the previous calculation, and use them in a new calculation. You could redo the calculation in the same directory, but you risk losing the results of the first step. That can make it difficult to reproduce a result. We advocate our approach of using multiple directories for the subsequent calculations, because it leaves a clear trail of how the work was done.

Note:

The **RWIGS** is not uniquely determined for an element. There are various natural choices, e.g. the ionic radius of an atom, or a value that minimizes overlap of neighboring spheres, but these values can change slightly in different environments.

You can also get spin-polarized atom-projected DOS, and magnetization projected DOS. See http://cms.mpi.univie.ac.at/vasp/vasp/DOSCAR_-file.html#doscar for more details.

```

1  from jasp import *
2  from ase.dft.dos import DOS

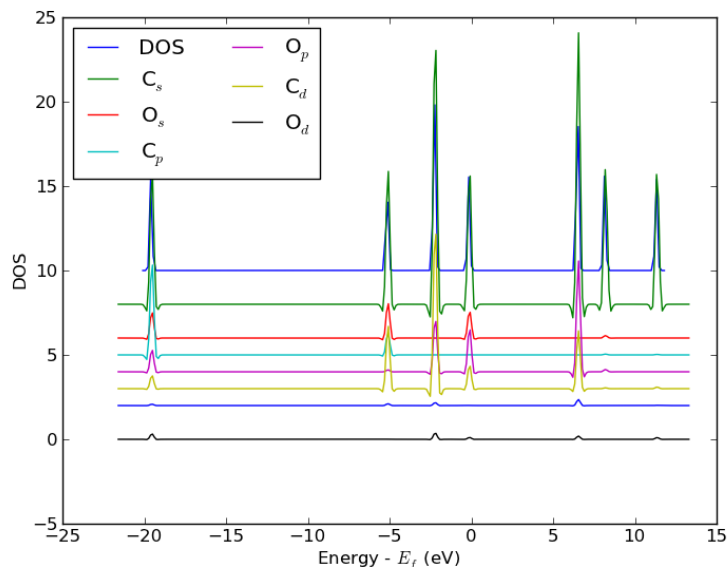

Figure 13: Atom-projected DOS for a CO molecule. The total density of states and the s , p and d states on the C and O are shown.

3.3.4 Visualizing electron density

The electron density is a $3d$ quantity: for every (x, y, z) point, there is a charge density. That means we need 4 numbers for each point: (x, y, z) and $\rho(x, y, z)$. Below we show an example (Figure 14) of plotting the charge density, and we consider some issues we have to consider when visualizing volumetric data in unit cells with periodic boundary conditions. We will use the results from a previous calculation.

```

3.3.6 Dipole moments

The **dipole moment** is a vector describing the separation of electrical (negative) and nuclear (positive) charge. The magnitude of this vector is the dipole moment, which has units of Coulomb-meter, or more commonly Debye. The symmetry of a molecule determines if a molecule has a dipole moment or not. Below we compute the dipole moment of CO. We must integrate the electron density to find the center of electrical charge, and sum over the nuclei to find the center of positive charge.

```

1  from jasp import *
2  from ase.units import Debye
3
4  with jasp('molecules/co-centered') as calc:
5      atoms.get_potential_energy()
6
7      vcd = VaspChargeDensity()
8
9      cd = np.array(vcd.chg[0])
10     n0, n1, n2 = cd.shape
11
12     s0 = 1.0/n0
13     s1 = 1.0/n1
14     s2 = 1.0/n2

```

Figure 16: Plot of the electrostatic potential of CF_3Br . TODO: figure out how to do an isosurface of charge, colormapped by the local potential.

```

15
16     X, Y, Z = np.mgrid[0.0:1.0:s0,
17                        0.0:1.0:s1,
18                        0.0:1.0:s2]
19
20     C = np.column_stack([X.ravel(),
21                          Y.ravel(),
22                          Z.ravel()])
23
24     atoms = calc.get_atoms()
25     uc = atoms.get_cell()
26     real = np.dot(C, uc)
27
28     #now convert arrays back to unitcell shape
29     x = np.reshape(real[:, 0], (n0, n1, n2))
30     y = np.reshape(real[:, 1], (n0, n1, n2))
31     z = np.reshape(real[:, 2], (n0, n1, n2))
32
33     nelements = n0 * n1 * n2
34     voxel_volume = atoms.get_volume() / nelements
35     total_electron_charge = -cd.sum() * voxel_volume
36
37
38     electron_density_center = np.array([(cd * x).sum(),
39                                         (cd * y).sum(),

```

```

40         (cd * z).sum())
41     electron_density_center *= voxel_volume
42     electron_density_center /= total_electron_charge
43
44     electron_dipole_moment = -electron_density_center * total_electron_charge
45
46     # now the ion charge center. We only need the Zval listed in the potcar
47     from jasp.POTCAR import get_ZVAL
48
49     LOP = calc.get_pseudopotentials()
50     ppp = os.environ['VASP_PP_PATH']
51
52     zval = {}
53     for sym, ppath, hash in LOP:
54         fullpath = os.path.join(ppp, ppath)
55         z = get_ZVAL(fullpath)
56         zval[sym] = z
57     ion_charge_center = np.array([0.0, 0.0, 0.0])
58     total_ion_charge = 0.0
59     for atom in atoms:
60         Z = zval[atom.symbol]
61         total_ion_charge += Z
62         pos = atom.position
63         ion_charge_center += Z*pos
64
65     ion_charge_center /= total_ion_charge
66     ion_dipole_moment = ion_charge_center * total_ion_charge
67
68     dipole_vector = (ion_dipole_moment + electron_dipole_moment)
69
70     dipole_moment = ((dipole_vector**2).sum())**0.5 / Debye
71
72     print 'The dipole moment is {0:1.2f} Debye'.format(dipole_moment)

```

The dipole moment is 0.10 Debye

Note that a function using the code above exists in `jasp` which makes it trivial to compute the dipole moment. Here is an example of its usage.

```

1  from jasp import *
2  from ase.units import Debye
3
4  with jasp('molecules/co-centered') as calc:
5      dipole_vector = calc.get_dipole_moment()
6      dipole_moment = ((dipole_vector**2).sum())**0.5/Debye
7      print 'The dipole moment is {0:1.2f} Debye'.format(dipole_moment)

```

The dipole moment is 0.10 Debye

3.3.7 Bader analysis

Bader analysis is a charge partitioning scheme where charge is divided by surfaces of zero flux that define atomic basins of charge. The most modern way of calculating the Bader charges is using the `bader` program from Graeme Henkelmen's group.^{41;42} Let us consider a water molecule, centered in a box. The strategy is first to run the calculation, then run the `bader` program on the results.

```

1  from jasp import *
2  from ase.structure import molecule
3  atoms = molecule('H2O')
4  atoms.center(vacuum=6)
5
6  with jasp('molecules/h2o-bader',
7           xc='PBE',
8           encut=350,
9           atoms=atoms) as calc:
10     calc.calculate()
11
12     os.system('bader -p all_atom -p atom_index CHG')

```

This script should work, but only if displacement is set to None or we convert the positions to Bohr. Otherwise, the positions do not match because of a Bohr/Angstrom units problem in an assertions statement. Note the complex sorting that has to be done, because the order of atoms in the Atoms object is not the same as in the POSCAR file.

```

O	0.001

TODO: figure out these charges

3.4 Geometry optimization

3.4.1 Bond lengths

Manual determination The equilibrium bond length of a CO molecule is approximately the bond length that minimizes the total energy. We can find that by computing the total energy as a function of bond length, and noting where the minimum is. Here is an example in VASP. There are a few features to point out here. We want to compute 5 bond lengths, and each calculation is independent of all the others. `jasp` is setup to automatically handle jobs for you by submitting them to the queue. It raises a variety of exceptions to let you know what has happened, and you must handle these to control the workflow. We will illustrate this by the following examples.

```

1 from jasp import *
2 from ase import Atom, Atoms
3 import numpy as np
4 np.set_printoptions(precision=3,suppress=True)
5
6 bond_lengths = [1.05, 1.1, 1.15, 1.2, 1.25]
7 energies = []
8
9 for d in bond_lengths: #possible bond lengths
10
11     co = Atoms([Atom('C', [0, 0, 0]),
12                 Atom('O', [d, 0, 0])],
13                cell=(6, 6, 6))
14
15     with jasp('molecules/co-{0}'.format(d), #output dir

```

```

16         xc='PBE',
17         nbands=6,
18         encut=350,
19         ismear=1,
20         sigma=0.01,
21         atoms=co):
22     try:
23         e = co.get_potential_energy()
24         energies.append(e)
25         print 'd = {0:1.2f} ang'.format(d)
26         print 'energy = {0:1.3f} eV'.format(e)
27         print 'forces = (eV/ang)\n {0}'.format(co.get_forces())
28         print '' #blank line
29     except (VaspSubmitted, VaspQueued):
30         energies.append(None)
31     pass
32
33 if not None in energies:
34     import matplotlib.pyplot as plt
35     plt.plot(bond_lengths, energies, 'bo-')
36     plt.xlabel('Bond length (Å)')
37     plt.ylabel('Total energy (eV)')
38     plt.savefig('images/co-bondlengths.png')

```

```

d = 1.05 ang
energy = -14.215189 eV
forces = (eV/ang)
[[-14.903  0.      0.   ]
 [ 14.903  0.      0.   ]]

```

```

d = 1.10 ang
energy = -14.719882 eV
forces = (eV/ang)
[[-5.8  0.   0. ]
 [ 5.8  0.   0. ]]

```

```

d = 1.15 ang
energy = -14.838448 eV
forces = (eV/ang)
[[ 0.645  0.      0.   ]
 [-0.645  0.      0.   ]]

```

```

d = 1.20 ang
energy = -14.687906 eV
forces = (eV/ang)
[[ 5.095  0.      0.   ]
 [-5.095  0.      0.   ]]

```

```

d = 1.25 ang
energy = -14.351675 eV
forces = (eV/ang)
[[ 8.141  0.      0.   ]
 [-8.141  0.      0.   ]]

```

To find the minimum we could run more calculations, but a simpler and faster way is to fit a polynomial to the data, and find the analytical minimum. The results are shown in Figure 17.

```

1  from jasp import *
2  import numpy as np
3  import matplotlib.pyplot as plt
4  np.set_printoptions(precision=3,suppress=True)
5
6  bond_lengths = [1.05, 1.1, 1.15, 1.2, 1.25]
7  energies = []
8
9  for d in bond_lengths: #possible bond lengths
10
11      with jasp('molecules/co-{0}'.format(d)) as calc:

13          energies.append(atoms.get_potential_energy())
14
15  # Now we fit an equation - cubic polynomial
16  pp = np.polyfit(bond_lengths, energies, 3)
17  dp = np.polyder(pp) # first derivative - quadratic
18
19  # we expect two roots from the quadratic eqn. These are where the
20  # first derivative is equal to zero.
21  roots = np.roots(dp)
22
23  # The minimum is where the second derivative is positive.
24  dpp = np.polyder(dp) # second derivative - line
25  secd = np.polyval(dpp, roots)
26
27  minV = roots[secd > 0]
28  minE = np.polyval(pp, minV)
29
30  print 'The minimum energy is {0} eV at V = {1} Ang^3'.format(minE,minV)
31
32  # plot the fit
33  x = np.linspace(1.05, 1.25)
34  fit = np.polyval(pp, x)
35
36  plt.plot(bond_lengths, energies, 'bo ')
37  plt.plot(x,fit, 'r-')
38  plt.plot(minV, minE, 'm* ')
39  plt.legend(['DFT','fit','minimum'], numpoints=1)
40  plt.xlabel('Bond length ($\AA$)')
41  plt.ylabel('Total energy (eV)')
42  plt.savefig('images/co-bondlengths.png')
43  plt.show()

```

Figure 17: Energy vs CO bond length.

Automatic geometry optimization with VASP It is generally the case that the equilibrium geometry of a system is the one that minimizes the total energy and forces. Since each atom has three degrees of freedom, you can quickly get a high dimensional optimization problem. Luckily, VASP has built-in geometry optimization using the [IBRION](#) and [NSW](#) tags. Here we compute the bond length for a CO molecule, letting VASP do the geometry optimization for us.

```

1  from ase import Atom, Atoms

3.5 Vibrational frequencies

3.5.1 Manual calculation of vibrational frequency

The principle idea in calculating vibrational frequencies is that we consider a molecular system as masses connected by springs. If the springs are Hookean, e.g. the force is proportional to the displacement, then we can readily solve the equations of motion and find that the vibrational frequencies are related to the force constants and the masses of the atoms. For example, in a simple molecule like CO where there is only one spring, the frequency is:

$\nu = \frac{1}{2\pi} \sqrt{k/\mu}$ where $\frac{1}{\mu} = \frac{1}{m_C} + \frac{1}{m_O}$ and k is the spring constant. We will compute the value of k from DFT calculations as follows:

$k = \frac{\partial^2 E}{\partial x^2}$ at the equilibrium bond length. We actually already have the data to do this from [Manual determination](#). We only need to fit an equation to the energy vs. bond-length data, find the minimum energy bond-length, and then evaluate the second derivative of the fitted function at the minimum. We will use a cubic polynomial for demonstration here. Polynomials are numerically convenient because they are easy to fit, and it is trivial to get the roots and

derivatives of the polynomials, as well as to evaluate them at other points using `numpy.polyfit`, `numpy.polyder`, and `numpy.polyval`.

```

1  from jasp import *
2  from ase.units import *
3
4  bond_lengths = [1.05, 1.1, 1.15, 1.2, 1.25]
5  energies = []
6
7  for d in bond_lengths:
8      with jasp('molecules/co-{0}'.format(d)) as calc:
9          atoms = calc.get_atoms()
10         energies.append(atoms.get_potential_energy())
11
12  # fit the data
13  pars = np.polyfit(bond_lengths, energies, 3)
14  xfit = np.linspace(1.05, 1.25)
15  efit = np.polyval(pars, xfit)
16
17  # first derivative
18  dpars = np.polyder(pars)
19  # find where the minimum is. chose the second one because it is the
20  # minimum we need.
21  print 'roots of first derivative are {0}'.format(np.roots(dpars))
22
23  d_min = 1.14425395 # we manually copy this from the output to here
24  # second derivative
25  ddpars = np.polyder(dpars)
26
27  #curvature at minimum = force constant
28  k = np.polyval(ddpars, d_min) / kg * s**2
29
30  # reduced mass
31  from ase.data import atomic_masses
32  C_mass = atomic_masses[6] / kg
33  O_mass = atomic_masses[8] / kg
34
35  mu = (C_mass*O_mass)/(C_mass + O_mass)
36
37  frequency = 1. / (2. * np.pi) * np.sqrt(k / mu)
38  print 'The CO vibrational frequency is {0} cm^{-1}'.format(frequency/3e10)
39
40  import matplotlib.pyplot as plt
41  plt.plot(bond_lengths, energies, 'bo ')
42  plt.plot(xfit, efit, 'b-')
43  plt.xlabel('Bond length (Å)')
44  plt.ylabel('Total energy (eV)')
45  plt.show()

```

```

roots of first derivative are [ 1.43384501  1.14425395]
The frequency is 2143.60766258 cm^{-1}

```

This result is in good agreement with [experiment](#). The procedure described above is basically how many vibrational calculations are performed. With more atoms, you have to determine a force constant matrix and diagonalize it. For more details, see. ⁴³ In practice, we usually allow a packaged code to automate this, which we cover in [Automated vibrational calculations](#)

We now consider how much energy is in this vibration. This is commonly called zero-point energy (ZPE) and it is defined as $E_{ZPE} = \frac{1}{2}h\nu$ for a single mode, and h is Planck's constant (4.135667516e-15 eV/s).

```

1 c = 3e10 # speed of light cm/s
2 h = 4.135667516e-15 # eV/s
3
4 nu = 2143.6076625*c # 1/s
5
6 E_zpe = 0.5*h*nu
7
8 print 'E_ZPE = {0:1.3f} eV'.format(E_zpe)

```

E_ZPE = 0.133 eV

This is a reasonable amount of energy! Zero-point energy increases with increasing vibrational frequency, and tends to be very important for small atoms.

A final note is that this analysis is in the “harmonic approximation”. The frequency equation is the solution to a harmonic oscillator. If the spring is non-linear, then there are anharmonic effects that may become important, especially at higher temperatures.

3.5.2 Automated vibrational calculations

VASP has built-in capability for performing vibrational calculations.

Note we get 9 frequencies here. Water has 3 atoms, with three degrees of freedom each, leading to 9 possible combinations of collective motions. Three of those collective motions are translations, i.e. where all atoms move in the same direction (either x , y or z) and there is no change in the total energy of the molecule. Another three of those motions are rotations, which also do not change the total energy of the molecule. That leaves $3N-6 = 3$ degrees of vibrational freedom where some or all of the bonds are stretched, resulting in a change in the total energy. The modes of water vibration are (with our calculated values in parentheses):

1. a symmetric stretch at 3657 cm^{-1} (3723)
2. an asymmetric stretch at 3756 cm^{-1} (3836)
3. and a bending mode at 1595 cm^{-1} (1583)

<http://webbook.nist.gov/cgi/cbook.cgi?ID=C7732185&Mask=800#Electronic-Spec>

The results are not too far off, and more accurate frequencies may be possible using tighter tolerance on **POTIM**, or by using **IBRION**=7 or 8.

Let us briefly discuss how to determine which vectors are vibrations and which are rotations or translations. http://www.gaussian.com/g_whitepap/vib.htm

```
1 from jasp import *
2 import numpy as np
3 with jasp('molecules/h2o_vib') as calc:
4     atoms = calc.get_atoms()
5     masses = atoms.get_masses()
6     energies, modes = calc.get_vibrational_modes()
7
8 # translations

```

Zero-point energy for multiple modes For a molecule with lots of vibrational modes the zero-point energy is defined as the sum over all the vibrational modes:

$$E_{ZPE} = \sum_i \frac{1}{2} h \nu_i$$

Here is an example for water. Note we do not sum over the imaginary modes. We should also ignore the rotational and translational modes (some of those are imaginary, but some are just small).

```

1  from jasp import *
2  import numpy as np
3  c = 3e10 # speed of light cm/s
4  h = 4.135667516e-15 # eV/s
5
6  # first, get the frequencies.
7  with jasp('molecules/h2o_vib') as calc:
8      freq = calc.get_vibrational_frequencies()
9
10 ZPE = 0.0
11 for f in freq:
12     if not isinstance(f, float):
13         continue # skip complex numbers
14     nu = f*c # convert to frequency
15     ZPE += 0.5*h*nu
16
17 print 'The ZPE of water is {0:1.3f} eV'.format(ZPE)
18
19 # one liner
20 ZPE = np.sum([0.5*h*f*c for f in freq if isinstance(f, float)])
21 print 'The ZPE of water is {0:1.3f} eV'.format(ZPE)

```

The ZPE of water is 0.571 eV

Note the zero-point energy of water is also fairly high (more than 0.5 eV). That is because of the high frequency O-H stretches.

3.6 Simulated infrared spectra

At <http://homepage.univie.ac.at/david.karhanek/downloads.html#Entry02> there is a recipe for computing the Infrared vibrational spectroscopy intensities in VASP. We are going to do that for water here. First, we will relax a water molecule.

```

1  from ase import Atoms, Atom

```

Next, we instruct VASP to compute the vibrational modes using [density functional perturbation theory](#) with IBRION=7. Note, this is different than in [Vibrational frequencies](#) where finite differences were used.

```

1 from ase import Atoms, Atom
2 from jasp import *
3
4 #read in relaxed geometry
5 with jasp('molecules/h2o_relax') as calc:
6     atoms = calc.get_atoms()
7
8 # now define a new calculator
9 with jasp('molecules/h2o_vib_dfpt',
10         xc='PBE',
11         encut=400,
12         ismear=0, # Gaussian smearing
13         ibrion=7, # switches on the DFPT vibrational analysis (with
14                 # no symmetry constraints)
15         nfree=2,
16         potim=0.015,
17         lepsilon=True, # enables to calculate and to print the BEC
18                     # tensors
19         lreal=False,
20         nsw=1,
21         nwrite=3, # affects OUTCAR verbosity: explicitly forces
22                 # SQR(mass)-divided eigenvectors to be printed
23         atoms=atoms) as calc:
24     calc.calculate(atoms)

```

To analyze the results, this [shell script](#) was provided to extract the results.

```

1 #!/bin/bash
2 # A utility for calculating the vibrational intensities from VASP output (OUTCAR)
3 # (C) David Karhanek, 2011-03-25, ICIQ Tarragona, Spain (www.iciq.es)

```

The interpretation of these results is that the mode at 3713 cm^{-1} would be nearly invisible in the IR spectrum. Earlier we interpreted that as the symmetric stretch. In this mode, there is only a small change in the molecule dipole moment, so there is a small IR intensity.

See also. ⁴⁴ For HREELS simulations see. ⁴⁵

The shell script above has been translated to a convenient python function in `jasp`.

```

1 from jasp import *
2 with jasp('molecules/h2o_vib_dfpt') as calc:
3     print 'mode Relative intensity'
4     for i, intensity in enumerate(calc.get_infrared_intensities()):
5         print '{0:02d}      {1:1.3f}'.format(i, intensity)

```

mode	Relative intensity

3.7 Thermochemical properties of molecules

`ase` provides a [thermochemistry](#) module.

```

1 from ase.structure import molecule
2 from ase.thermochemistry import IdealGasThermo
3 from jasp import *
4
5 atoms = molecule('N2')
6 atoms.set_cell((10,10,10), scale_atoms=False)
7
8 # first we relax a molecule
9 with jasp('molecules/n2-relax',
10         xc='PBE',
11         encut=300,
12         ibrion=2,

```

```

13         nsw=5,
14         atoms=atoms) as calc:
15     electronicenergy = atoms.get_potential_energy()
16
17     # next, we get vibrational modes
18     with jasp('molecules/n2-vib',
19             xc='PBE',
20             encut=300,
21             ibrion=6,
22             nfree=2,
23             potim=0.15,
24             nsw=1,
25             atoms=atoms) as calc:
26         calc.calculate()
27         vib_freq = calc.get_vibrational_frequencies() # in cm-1
28
29         #convert wavenumbers to energy
30         h = 4.1356675e-15 # eV*s
31         c = 3.0e10 #cm/s
32         vib_energies = [h*c*nu for nu in vib_freq]
33         print 'vibrational energies\n=====',
34         for i,e in enumerate(vib_energies):
35             print '{0:02d}: {1} eV'.format(i,e)
36
37     # # now we can get some properties. Note we only need one vibrational
38     # energy since there is only one mode. This example does not work if
39     # you give all the energies because one energy is zero.
40     thermo = IdealGasThermo(vib_energies=vib_energies[0:0],
41                             electronicenergy=electronicenergy, atoms=atoms,
42                             geometry='linear', symmetrynumber=2, spin=0)
43
44     # temperature in K, pressure in Pa, G in eV
45     G = thermo.get_free_energy(temperature=298.15, pressure=101325.)

3.8 Molecular reaction energies

3.8.1 O₂ dissociation

The first reaction we consider is a simple dissociation of oxygen molecule into two oxygen atoms: $\text{O}_2 \rightarrow 2\text{O}$. The dissociation energy is pretty straightforward to define: it is the energy of the products minus the energy of the reactant. $D = 2 * E_{\text{O}} - E_{\text{O}_2}$. It would appear that we simply calculate the energy of an oxygen atom, and the energy of an oxygen molecule and evaluate the formula. Let us do that.

Simple estimate of O₂ dissociation energy

```

1  from jasp import *
2  from ase import Atom, Atoms
3
4  atoms = Atoms([Atom('O',[5,5,5])],
5                cell=(10,10,10))
6
7  with jasp('molecules/O',
8            xc='PBE',
9            encut=400,
10           ismear=0,
11           atoms=atoms) as calc:
12     try:
13         E_O = atoms.get_potential_energy()
14     except (VaspSubmitted, VaspQueued):
15         E_O = None
16
17     # now relaxed O2 dimer
18     atoms = Atoms([Atom('O',[5,5,5]),
19                   Atom('O',[6.22, 5,5])],
20                   cell=(10,10,10))
21
22     with jasp('molecules/O2',
23             xc='PBE',
24             encut=400,
```

```

25         ismear=0,
26         ibrion=2,
27         nsw=10,
28         atoms=atoms) as calc:
29     try:
30         E_O2 = atoms.get_potential_energy()
31     except (VaspSubmitted, VaspQueued):
32         E_O2 = None
33
34 if None not in (E_O, E_O2):
35     print 'O2 -> 2O   D = {0:1.3f} eV'.format(2*E_O - E_O2)

```

O2 -> 2O D = 8.521 eV

The answer we have obtained is way too high! Experimentally the dissociation energy is about 5.2 eV (need reference), which is **very** different than what we calculated! Let us consider some factors that contribute to this error.

We implicitly neglected spin-polarization in the example above. That could be a problem, since the O₂ molecule can be in one of two spin states, a singlet or a triplet, and these should have different energies. Furthermore, the oxygen atom can be a singlet or a triplet, and these would have different energies. To account for spin polarization, we have to tell VASP to use spin-polarization, and give initial guesses for the magnetic moments of the atoms. Let us try again with spin polarization.

Estimating O₂ dissociation energy with spin polarization in triplet ground states

To tell VASP to use spin-polarization we use `ISPIN=2`, and we set initial guesses for magnetic moments on the atoms with the `magmom` keyword. In a triplet state there are two electrons with spins of the same sign.

```

1  from jasp import *
2  from ase import Atom, Atoms
3
4  atoms = Atoms([Atom('O', [5,5,5], magmom=2)],
5                cell=(10,10,10))
6
7  with jasp('molecules/O2-sp-triplet',
8            xc='PBE',
9            encut=400,
10           ismear=0,
11           ispin=2,
12           atoms=atoms) as calc:
13     try:
14         E_O = atoms.get_potential_energy()
15     except (VaspSubmitted, VaspQueued):
16         E_O = None
17
18 print 'Magnetic moment on O = {0} Bohr magnetons'.format(atoms.get_magnetic_moment())
19
20 # now relaxed O2 dimer
21 atoms = Atoms([Atom('O', [5,5,5], magmom=1),
22               Atom('O', [6.22, 5,5], magmom=1)],
23               cell=(10,10,10))
24
25 with jasp('molecules/O2-sp-triplet',
26           xc='PBE',
27           encut=400,
28           ismear=0,
29           ispin=2, # turn spin-polarization on

```

```

30         ibrion=2, # make sure we relax the geometry
31         nsw=10,
32         atoms=atoms) as calc:
33     try:
34         E_O2 = atoms.get_potential_energy()
35     except (VaspSubmitted, VaspQueued):
36         E_O2 = None
37
38     # verify magnetic moment
39     print 'Magnetic moment on O2 = {0} Bohr magnetons'.format(atoms.get_magnetic_moment())
40
41     if None not in (E_O, E_O2):
42         print 'O2 -> 20 D = {0:1.3f} eV'.format(2*E_O - E_O2)

```

```

Magnetic moment on O = 2.0000072 Bohr magnetons
Magnetic moment on O2 = 2.0000083 Bohr magnetons
O2 -> 20 D = 6.668 eV

```

This is much closer to accepted literature values for the DFT-GGA O₂ dissociation energy. It is still more than 1 eV above an experimental value, but most of that error is due to the GGA exchange correlation functional. Some additional parameters that might need to be checked for convergence are the SIGMA value (it is probably too high for a molecule), as well as the cutoff energy. Oxygen is a “hard” atom that requires a high cutoff energy to achieve high levels of convergence.

TODO: show what “hard or soft” is in the pseudopotential.

Looking at the two spin densities In a spin-polarized calculation there are actually two electron densities: one for spin-up and one for spin-down. We will look at the differences in these two through the density of states.

```

1  from jasp import *
2  from ase.dft.dos import *
3
4  with jasp('molecules/O2-sp-triplet') as calc:
5      dos = DOS(calc, width=0.2)
6      d_up = dos.get_dos(spin=0)
7      d_down = dos.get_dos(spin=1)
8      e = dos.get_energies()
9
10     ind = e <= 0.0
11     # integrate up to 0eV
12     print 'number of up states = {0}'.format(np.trapz(d_up[ind], e[ind]))
13     print 'number of down states = {0}'.format(np.trapz(d_down[ind], e[ind]))
14
15     import pylab as plt
16     plt.plot(e, d_up,
17              e, -d_down)
18     plt.xlabel('energy [eV]')
19     plt.ylabel('DOS')
20     plt.legend(['up', 'down'])
21     plt.savefig('images/O2-sp-dos.png')

```

```

number of up states = 7.00000343617
number of down states = 5.00001715094

```

Figure 18: Spin-polarized DOS for the O₂ molecule.

You can see in Figure 18 that there are two different densities of states for the two spins. One has 7 electrons in it (the blue lines), and the other has 5 electrons in it (the green line). The difference of two electrons leads to the magnetic moment of 2 which we calculated earlier. Remember that only peaks in the DOS below the Fermi level are occupied. It is customary to set the Fermi level to 0 eV in DOS plots. The peaks roughly correspond to electrons. For example, the blue peak between -25 and -30 eV corresponds to one electron, in a 1s orbital, where as the blue peak between -5 and -10 eV corresponds to three electrons.

Convergence study of the O₂ dissociation energy

```

```

Figure 19: Convergence study of the O₂ dissociation energy as a function of ENCUT.

Based on these results (Figure 19), you could argue the dissociation energy is converged to about 2 meV at a planewave cutoff of 450 eV, and within 50 meV at 350 eV cutoff. You have to decide what an appropriate level of convergence is. Note that increasing the planewave cutoff significantly increases the computational time, so you are balancing level of convergence with computational speed. It would appear that planewave cutoff is not the cause for the discrepancy between our calculations and literature values.

Illustration of the effect of SIGMA The methodology for extrapolation of the total energy to absolute zero is only valid for a continuous density of states at the Fermi level.¹¹ Consequently, it should not be used for semiconductors, molecules or atoms. In VASP, this means a very small Fermi temperature (SIGMA) should be used. The O₂ dissociation energy as a function of SIGMA is shown in Figure 20. A variation of nearly 0.2 eV is seen from the default Fermi temperature of $k_bT = 0.2$ eV and the value of $k_bT = 0.0001$ eV. However, virtually no change was observed for a hydrogen atom or molecule or for an oxygen molecule as a function of the Fermi temperature. It is recommended that the total energy be calculated at several values of the Fermi temperature to make sure the total energy is converged with respect to the Fermi temperature.

We were not careful in selecting a good value for SIGMA in the calculations above. The default value of SIGMA is 0.2, which may be fine for metals, but it is not correct for molecules. SIGMA is the broadening factor used to smear the electronic density of states at the Fermi level. For a metal with a continuous density of states this is appropriate, but for molecules with discrete energy states it does not make sense. We are somewhat forced to use the machinery designed for metals on molecules. The solution is to use a very small SIGMA. Ideally you would

use SIGMA=0, but that is not practical for convergence reasons, so we try to find what is small enough. Let us examine the effect of SIGMA on the dissociation energy here.

```

Figure 20: Effect of SIGMA on the oxygen dissociation energy.

Clearly SIGMA has an effect, but it does not move the dissociation energy closer to the literature values!

Estimating triplet oxygen dissociation energy with low symmetry It has been suggested that breaking spherical symmetry of the atom can result in lower energy of the atom. The symmetry is broken by putting the atom off-center in a box. We will examine the total energy of an oxygen atom in a few geometries. First, let us consider variations of a square box.

```

1  from jasp import *
2  from ase import Atom, Atoms
3
4  # square box origin
5  atoms = Atoms([Atom('O', [0, 0, 0], magmom=2)],
6                cell=(10, 10, 10))
7
8  with jasp('molecules/0-square-box-origin',
9            xc='PBE',
10           encut=400,
11           ismear=0,
12           sigma=0.01,
13           ispin=2,
14           atoms=atoms) as calc:
15     try:

```

Orthorhombic box (origin): E = -1.8941 eV
 Orthorhombic box (center): E = -1.894124 eV
 Orthorhombic box (random): E = -1.494285 eV

This is a surprisingly large difference in energy! Nearly 0.4 eV. This is precisely the amount of energy we were in disagreement with the literature values. Surprisingly, the “random” position is higher in energy, similar to the cubic boxes. Finally, we put this all together. We use a non-symmetric box for the O-atom.

```

1  from jasp import *
2  from ase import Atom, Atoms
3
4  atoms = Atoms([Atom('O', [5.1, 4.2, 6.1], magmom=2)],

40         E_O2 = None
41
42 if None not in (E_O, E_O2):
43     print 'E_O: ', E_O
44     print 'O2 -> 2O   D = {0:1.3f} eV'.format(2*E_O - E_O2)

```

```

Magnetic moment on O = 2.0000016 Bohr magnetons
Magnetic moment on O2 = 2.0000083 Bohr magnetons
E_O:  -1.893571
O2 -> 2O   D = 6.061 eV

```

This actually agrees within 30-50 meV of reported literature values, although still nearly an eV greater than the experimental dissociation energy. Note that with a different “random” position, we get the lower energy for the O atom. All the disagreement we had been seeing was apparently in the O atom energy. So, if you do not need the dissociation energy in your analysis, you will not see the error. Also note that this error is specific to there being a spherical atom in a symmetric cell. This is not a problem for most molecules, which are generally non-spherical.

Estimating singlet oxygen dissociation energy Finally, let us consider the case where each species is in the singlet state.

```

1  from jasp import *
2  from ase import Atom, Atoms
3
4  atoms = Atoms([Atom('O', [5, 5, 5], magmom=0)],

15      except (VaspSubmitted, VaspQueued):
16          E_O = None
17
18  print 'Magnetic moment on O = {0} Bohr magnetons'.format(atoms.get_magnetic_moment())
19
20  # now relaxed O2 dimer
21  atoms = Atoms([Atom('O', [5, 5, 5], magmom=1),
22               Atom('O', [6.22, 5, 5], magmom=-1)],
23               cell=(10, 10, 10))
24
25  with jasp('molecules/O2-sp-singlet',
26           xc='PBE',

```

```

27         encut=400,
28         ismear=0,
29         ispin=2, # turn spin-polarization on
30         ibrion=2, # make sure we relax the geometry
31         nsw=10,
32         atoms=atoms) as calc:
33     try:
34         E_02 = atoms.get_potential_energy()
35     except (VaspSubmitted, VaspQueued):
36         E_02 = None
37
38     # verify magnetic moment
39     print atoms.get_magnetic_moment()
40
41 if None not in (E_0, E_02):
42     print '02 -> 20   D = {0:1.3f} eV'.format(2*E_0 - E_02)

```

```

Magnetic moment on 0 = 1.9998232 Bohr magnetons
0.0
02 -> 20   D = 5.650 eV

```

Interestingly, Vasp still found a triplet spin state on the oxygen atom, even though we guessed an initial magnetic moment of 0. This highlights a difficulty in computing magnetic moments: you provide an initial guess and a solution is found. The magnetic moment of a singlet state is zero, so the molecule is correct. Also interesting is that the dissociation energy is almost equal to the experimental value. This is probably a coincidence, and may reflect the fact that the singlet oxygen state is less stable than the triplet state. Let us directly compare their total energies:

```

1 from jasp import *
2
3 with jasp('molecules/02-sp-singlet') as calc:
4     print 'singlet: {0} eV'.format(calc.get_atoms().get_potential_energy())
5
6 with jasp('molecules/02-sp-triplet') as calc:
7     print 'triplet: {0} eV'.format(calc.get_atoms().get_potential_energy())

```

```

singlet:  -8.830101
triplet:  -9.848238

```

You can see here the triplet state has an energy that is 1 eV more stable than the singlet state.

Verifying the magnetic moments on each atom It is one thing to see the total magnetic moment of a singlet state, and another to ask what are the magnetic moments on each atom. In VASP you must use `LORBIT=11` to get the magnetic moments of the atoms written out.

```

1 from jasp import *
2 from ase import Atom, Atoms
3
4 with jasp('molecules/02-sp-singlet') as calc:
5     calc.clone('molecules/02-sp-singlet-magmoms')
6
7 with jasp('molecules/02-sp-singlet-magmoms') as calc:

```

```

8     calc.set(lorbit=11)
9     atoms = calc.get_atoms()
10    magmoms = atoms.get_magnetic_moments()
11
12    print 'singlet ground state'
13    for i,atom in enumerate(atoms):
14        print 'atom {0}: magmom = {1}'.format(i, magmoms[i])
15    print atoms.get_magnetic_moment()
16
17    with jasp('molecules/O2-sp-triplet') as calc:
18        calc.clone('molecules/O2-sp-triplet-magmoms')
19
20    with jasp('molecules/O2-sp-triplet-magmoms') as calc:
21        calc.set(lorbit=11)
22        atoms = calc.get_atoms()
23        magmoms = atoms.get_magnetic_moments()
24        print
25        print 'triplet ground state'
26        for i,atom in enumerate(atoms):
27            print 'atom {0}: magmom = {1}'.format(i, magmoms[i])
28        print atoms.get_magnetic_moment()

```

```

singlet ground state
atom 0: magmom = 0.0
atom 1: magmom = 0.0
0.0

```

```

triplet ground state
atom 0: magmom = 0.815
atom 1: magmom = 0.815
2.0000084

```

Note the atomic magnetic moments do not add up to the total magnetic moment. The atomic magnetic moments are not really true observable properties. The moments are determined by a projection method that probably involves a spherical orbital, so the moments may be over or underestimated.

Using a different potential It is possible we need a higher quality potential to get the 6.02 eV value quoted by many in the literature. Here we try the O_{sv} potential, which treats the 1s electrons as valence electrons. Note however, the ENMIN in the POTCAR is very high!

```

1  grep ENMIN $VASP_PP_PATH/potpaw_PBE/O_sv/POTCAR

```

```

ENMAX  = 1421.493; ENMIN  = 1066.119 eV

```

In the following calculation, we let VASP select an appropriate ENCUT value.

```

1  from jasp import *
2  from ase import Atom, Atoms
3
4  atoms = Atoms([Atom('O', [4, 4.5, 5], magmom=2)],
5               cell=(8, 9, 10))
6
7  with jasp('molecules/O-sp-triplet-lowsym-sv',

```

```

8         xc='PBE',
9         ismear=0,
10        ispin=2,
11        sigma=0.01,
12        setups={'O': '_sv'},
13        atoms=atoms) as calc:
14    try:
15        E_0 = atoms.get_potential_energy()
16    except (VaspSubmitted, VaspQueued):
17        E_0 = None
18
19    print 'Magnetic moment on O = {0} Bohr magnetons'.format(atoms.get_magnetic_moment())
20
21    # now relaxed O2 dimer
22    atoms = Atoms([Atom('O', [5, 5, 5], magmom=1),
23                  Atom('O', [6.22, 5, 5], magmom=1)],
24                  cell=(10, 10, 10))
25
26    with jasp('molecules/O2-sp-triplet-sv',
27             xc='PBE',
28             ismear=0,
29             sigma=0.01,
30             ispin=2, # turn spin-polarization on
31             ibrion=2, # make sure we relax the geometry
32             nsw=10,
33             setups={'O': '_sv'},
34             atoms=atoms) as calc:
35        try:
36            E_O2 = atoms.get_potential_energy()
37        except (VaspSubmitted, VaspQueued):
38            E_O2 = None
39
40    # verify magnetic moment
41    print 'Magnetic moment on O2 = {0} Bohr magnetons'.format(atoms.get_magnetic_moment())
42
43    if None not in (E_0, E_O2):
44        print 'O2 -> 2O   D = {0:1.3f} eV'.format(2*E_0 - E_O2)

```

```

Magnetic moment on O = 2.0000001 Bohr magnetons
Magnetic moment on O2 = 1.9999996 Bohr magnetons
O2 -> 2O   D = 6.299 eV

```

This result is close to other reported values. It is possibly not converged, since we let VASP choose the ENCUT value, and that value is the ENMIN value in the POTCAR. Nevertheless, the point is that a harder potential does not fix the problem of overbinding in the O₂ molecule. That is a fundamental flaw in the GGA exchange-correlation functional.

3.8.2 Water gas shift example

We consider calculating the reaction energy of the water-gas shift reaction in this example.

We define the reaction energy as the difference in energy between the products and reactants.

$$\Delta E = E_{\text{CO}_2} + E_{\text{H}_2} - E_{\text{CO}} - E_{\text{H}_2\text{O}}$$

For now, we compute this energy simply as the difference in DFT energies. In the next section we will add zero-point energies and compute the energy difference as a function of temperature. For now, we simply need to compute the total energy of each molecule in its equilibrium geometry.

```

1  from ase.data.molecules import molecule
2  from jasp import *
3
4  # first we define our molecules. These will automatically be at the coordinates from the G2 database.
5
6  C0 = molecule('C0')
7  C0.set_cell([8, 8, 8], scale_atoms=False)
8
9  H2O = molecule('H2O')
10 H2O.set_cell([8, 8, 8], scale_atoms=False)
11
12 CO2 = molecule('CO2')
13 CO2.set_cell([8, 8, 8], scale_atoms=False)
14
15 H2 = molecule('H2')
16 H2.set_cell([8, 8, 8], scale_atoms=False)
17
18 # now the calculators to get the energies
19 with jasp('molecules/wgs/C0',
20          xc='PBE',
21          encut=350,
22          ismear=0,
23          ibrion=2,
24          nsw=10,
25          atoms=C0) as calc:
26     try:
27         eC0 = C0.get_potential_energy()
28     except (VaspSubmitted, VaspQueued):
29         eC0 = None
30
31 with jasp('molecules/wgs/CO2',
32          xc='PBE',
33          encut=350,
34          ismear=0,
35          ibrion=2,
36          nsw=10,
37          atoms=CO2) as calc:
38     try:
39         eCO2 = CO2.get_potential_energy()
40     except (VaspSubmitted, VaspQueued):
41         eCO2 = None
42
43 with jasp('molecules/wgs/H2',
44          xc='PBE',
45          encut=350,
46          ismear=0,
47          ibrion=2,
48          nsw=10,
49          atoms=H2) as calc:
50     try:
51         eH2 = H2.get_potential_energy()
52     except (VaspSubmitted, VaspQueued):
53         eH2 = None
54
55 with jasp('molecules/wgs/H2O',
56          xc='PBE',
57          encut=350,
58          ismear=0,
59          ibrion=2,
60          nsw=10,
61          atoms=H2O) as calc:
62     try:
63         eH2O = H2O.get_potential_energy()
64     except (VaspSubmitted, VaspQueued):
65         eH2O = None

```

```

66
67 if None in (eCO2, eH2, eCO, eH2O):
68     pass
69 else:
70     dE = eCO2 + eH2 - eCO - eH2O
71     print 'Delta E = {0:1.3f} eV'.format(dE)
72     print 'Delta E = {0:1.3f} kcal/mol'.format(dE*23.06035)
73     print 'Delta E = {0:1.3f} kJ/mol'.format(dE*96.485)

```

```

\Delta E = -0.720 eV
\Delta E = -16.614 kcal/mol
\Delta E = -69.514 kJ/mol

```

We [estimated](#) the enthalpy of this reaction at standard conditions to be -41 kJ/mol using data from the NIST webbook, which is a fair bit lower than we calculated here. In the next section we will examine whether additional corrections are needed, such as zero-point and temperature corrections.

It is a good idea to verify your calculations and structures are what you expected. Let us print them here. Inspection of these results shows the geometries were all relaxed, i.e., the forces on each atom are less than 0.05 eV/Å.

```

3.8.3 Temperature dependent water gas shift equilibrium constant

To correct the reaction energy for temperature effects, we must compute the vibrational frequencies of each species, and estimate the temperature dependent contributions to vibrational energy and entropy. We will break these calculations into several pieces. First we do each vibrational calculation. After those are done, we can get the data and construct the thermochemistry objects we need to estimate the reaction energy as a function of temperature (at constant pressure).

CO vibrations

```

1  from jasp import *
2
3  # get relaxed geometry
4  with jasp('molecules/wgs/CO') as calc:
5      CO = calc.get_atoms()
6
7  # now do the vibrations
8  with jasp('molecules/wgs/CO-vib',
9          xc='PBE',
10         encut=350,
11         ismear=0,
12         ibrion=6,
13         nfree=2,

```

Water has $3N-6 = 3$ vibrational modes.

TODO Thermochemistry Now we are ready. We have the electronic energies and vibrational frequencies of each species in the reaction.

```

1  from ase.thermochemistry import IdealGasThermo
2  from jasp import *
3  import numpy as np
4  import matplotlib.pyplot as plt
5
6  # first we get the electronic energies
7  with jasp('molecules/wgs/CO') as calc:
8      CO = calc.get_atoms()
9      E_CO = CO.get_potential_energy()
10
11  with jasp('molecules/wgs/CO2') as calc:
12      CO2 = calc.get_atoms()
13      E_CO2 = CO2.get_potential_energy()
14
15  with jasp('molecules/wgs/H2') as calc:
16      H2 = calc.get_atoms()
17      E_H2 = H2.get_potential_energy()
18
19  with jasp('molecules/wgs/H2O') as calc:
20      H2O = calc.get_atoms()
21      E_H2O = H2O.get_potential_energy()
22
23  # now we get the vibrational energies
24  h = 4.1356675e-15 # eV*s
25  c = 3.0e10 #cm/s
26
27  with jasp('molecules/wgs/CO-vib') as calc:
28      vib_freq = calc.get_vibrational_frequencies()
29      CO_vib_energies = [h*c*nu for nu in vib_freq]
30
31  with jasp('molecules/wgs/CO2-vib') as calc:
32      vib_freq = calc.get_vibrational_frequencies()
33      CO2_vib_energies = [h*c*nu for nu in vib_freq]
34
35  with jasp('molecules/wgs/H2-vib') as calc:
36      vib_freq = calc.get_vibrational_frequencies()
37      H2_vib_energies = [h*c*nu for nu in vib_freq]
38
39  with jasp('molecules/wgs/H2O-vib') as calc:
40      vib_freq = calc.get_vibrational_frequencies()
41      H2O_vib_energies = [h*c*nu for nu in vib_freq]
42
43  # now we make a thermo object for each molecule
44  CO_t = IdealGasThermo(vib_energies=CO_vib_energies[0:0],
45                        electronicenergy=E_CO, atoms=CO,
46                        geometry='linear', symmetrynumber=1,

Figure 21: Thermodynamic energies of the water gas shift reaction as a function of temperature.

You can see a few things here. One is that at near 298K, the Gibbs free energy is about -40 kJ/mol. This is too negative for a standard state free energy, which we estimated to be about -29 kJ/mol from the [NIST webbook](#). There could be several reasons for this disagreement,

but the most likely one is errors in the exchange-correlation functional. Second, it appears the reaction enthalpy gets slightly more exothermic with temperature. This does not seem correct.

At 1000K we estimate the Gibbs free energy to be about -4 kJ/mol, compared to about -3 kJ/mol estimated from the NIST webbook.

Figure 22: Temperature dependence of the equilibrium constant.

Despite the error in ΔG , the equilibrium constant at 1000K seems reasonable. If you zoom in to 1000K you find the K_{eq} is about 1.5, and it is known to be 1.44 (see [this example](#)).

TODO something is wrong with the thermochemistry I think.

3.9 Molecular reaction barriers

We will consider a simple example of the barrier for NH_3 inversion. We have to create an NH_3 molecule in the initial and inverted state (these have exactly the same energy), and then interpolate a band of images. Then, we use the NEB method to compute the barrier to inversion.

3.9.1 Get initial and final states

```
1 # compute initial and final states
2 from ase import Atoms
3 from ase.data.molecules import molecule
4 import numpy as np
5 from jasp import *
```

```

6  from ase.constraints import FixAtoms
7
8  atoms = molecule('NH3')
9  constraint = FixAtoms(mask=[atom.symbol == 'N' for atom in atoms])
10 atoms.set_constraint(constraint)
11
12 Npos = atoms.positions[0]
13
14 # move N to origin
15 atoms.translate(-Npos)
16 atoms.set_cell((10, 10, 10), scale_atoms=False)
17
18 atoms2 = atoms.copy()
19 pos2 = atoms2.positions
20
21 for i,atom in enumerate(atoms2):
22     if atom.symbol == 'H':
23         # reflect through z
24         pos2[i] *= np.array([1, 1, -1])
25 atoms2.positions = pos2
26
27 #now move N to center of box
28 atoms.translate([5, 5, 5])
29 atoms2.translate([5, 5, 5])
30
31 with jasp('molecules/nh3-initial',
32         xc='PBE',
33         encut=350,
34         ibrion=1,
35         nsw=10,
36         atoms=atoms) as calc:
37     try:
38         calc.calculate()
39     except (VaspSubmitted, VaspQueued):
40         pass
41
42 with jasp('molecules/nh3-final',
43         xc='PBE',
44         encut=350,
45         ibrion=1,
46         nsw=10,
47         atoms=atoms2) as calc:
48     try:
49         calc.calculate()
50     except (VaspSubmitted, VaspQueued):
51         pass

```

3.9.2 Run band calculation

Now we do the band calculation.

```

1  # Run NH3 NEB calculations
2  from jasp import *
3  from ase.neb import NEB
4
5  with jasp('molecules/nh3-initial') as calc:
6      atoms = calc.get_atoms()
7
8  with jasp('molecules/nh3-final') as calc:
9      atoms2 = calc.get_atoms()
10
11 # 5 images including endpoints
12 images = [atoms]

```

```

13 images += [atoms.copy() for i in range(3)]
14 images += [atoms2]
15
16 neb = NEB(images)
17 neb.interpolate()
18
19 with jasp('molecules/nh3-neb',
20         xc='PBE',
21         ibrion=1,
22         nsw=90,
23         spring=-5,
24         atoms=images) as calc:
25     images, energies = calc.get_neb()
26
27     calc.plot_neb(show=False)
28 import matplotlib.pyplot as plt
29 plt.savefig('images/nh3-neb.png')

```

4 Bulk systems

See <http://arxiv.org/pdf/1204.2733.pdf> for a very informative comparison of DFT codes for computing different bulk properties.

4.1 Defining and visualizing bulk systems

4.1.1 Built-in functions in ase

As with molecules, `ase` provides several helper functions to create bulk structures. We highlight a few of them here.

```
1 from ase.io import write
2 from ase.lattice.cubic import FaceCenteredCubic
3
4 atoms = FaceCenteredCubic(directions=[[1,0,0],
5                                     [0,1,0],
6                                     [0,0,1]],
7                             size=(1,1,1),
8                             symbol='Ag',
9                             latticeconstant=4.0)
10
11 write('images/Ag-bulk.png',atoms,show_unit_cell=2)
12
13 # to make an alloy, we can replace one atom with another kind
14 atoms[0].symbol = 'Pd'
15 write('images/AgPd-bulk.png', atoms, show_unit_cell=2)
```

None

Figure 24: A simple fcc Ag bulk structure.

Figure 25: A simple Ag₃Pd bulk structure.

4.1.2 Using <http://materialsproject.org>

The [Materials Project](http://materialsproject.org) offers web access to a pretty large number of materials (over 21,000 at the time of this writing), including structure and other computed properties. You must sign

up for an account at the website, and then you can access the information. You can search for materials with lots of different criteria including formula, unit cell formula, by elements, by structure, etc... The website allows you to download the VASP files used to create the calculations. They also develop the [pymatgen](#) project (which requires python 2.7+).

For example, I downloaded this cif file for a RuO₂ structure (Material ID 825).

```

```

We can read this file in with `ase.io.read`. That function automatically recognizes the file type by the extension.

```

1  from ase.io import read, write
2
3  atoms = read('bulk/Ru2O4_1.cif')

```

```

4
5 write('images/Ru2O4.png', atoms, show_unit_cell=2)

```

Figure 26: An RuO₂ unit cell prepared from a cif file.

You can also download the VASP files. I have copied these files (INCAR, POSCAR, KPOINTS) to a directory (bulk/Ru2O4), and now we can run a calculation like this:

```

1 from jasp import *
2
3 with jasp('bulk/Ru2O4',
4           xc='PBE',
5           setups={'Ru': '_pv'}) as calc:
6     calc.calculate()
7     print calc

```

```

magmom: [0.6, 0.6, 0.6, 0.6, 0.6, 0.6]
prec: Accurate
algo: Fast
lreal: Auto
kpts: [8, 6, 6]
reciprocal: False
setups: {'Ru': '_pv'}
xc: PBE
txt: -
gamma: False

Pseudopotentials used:

Ru: potpaw_PBE/Ru_pv/POTCAR (git-hash: c29610ef9b7bfa353e710b09dfadcd2b0fb0d274)
O: potpaw_PBE/O/POTCAR (git-hash: 9a0489b46120b0cad515d935f44b5fbe3a3b1dfa)

Some notes: we had to specify the PBE functional. That is good habit, since the default may be something else. We also had to specify the special setups used, since those were not defaults either.

We get exactly the same result as the website! Why is this helpful then? Well, we could use this as a starting point to look at an equation of state, or to plot some interesting electronic structure, etc... Or we can gain a little confidence that our version of VASP is working like the one they used.

4.2 Determining bulk structures

What we typically mean by determining bulk structures includes the following:

- What is the most stable crystal structure for a material?
- What is the lattice constant of fcc Cu?

- What are the lattice parameters and internal atom parameters for TiO_2 ?

All of these questions can often be addressed by finding the volume, shape and atomic positions that minimize the total energy of a bulk system. This is true at 0K. At higher temperatures, one must consider minimizing the free energy, rather than the internal energy.

4.2.1 fcc/bcc crystal structures

The fcc and bcc structures are simple. They only have one degree of freedom: the lattice constant. In this section we show how to calculate the equilibrium volume of each structure, and determine which one is more stable. We start with the fcc crystal structure of Cu. We will manually define the crystal structure based on the definitions in Kittel³ (Chapter 1).

```

1 from jasp import *
2 from ase import Atom, Atoms
3
4 # fcc
5 LC = [3.5, 3.55, 3.6, 3.65, 3.7, 3.75]
6 fcc_energies = []
7 for a in LC:
8     atoms = Atoms([Atom('Cu', (0, 0, 0))],
9                   cell=0.5 * a*np.array([[1.0, 1.0, 0.0],
10                                         [0.0, 1.0, 1.0],
11                                         [1.0, 0.0, 1.0]]))
12
13     with jasp('bulk/Cu-{}'.format(a),
14              xc='PBE',
15              encut=350,
16              kpts=(8,8,8),
17              atoms=atoms) as calc:
18
19         e = atoms.get_potential_energy()
20         fcc_energies.append(e)
21
22 import matplotlib.pyplot as plt
23 plt.plot(LC, fcc_energies)
24 plt.xlabel('Lattice constant (Å)')
25 plt.ylabel('Total energy (eV)')
26 plt.savefig('images/Cu-fcc.png')
27
28 print '#+tblname: cu-fcc-energies'
29 print '| lattice constant (Å) | Total Energy (eV) |'
30 for lc, e in zip(LC, fcc_energies):
31     print '| {} | {} |'.format(lc, e)

```

lattice constant (Å)	Total Energy (eV)
3.5	-3.649238
3.55	-3.696204
3.6	-3.719946
3.65	-3.723951
3.7	-3.711284
3.75	-3.68426

Exercise 4.2

Use the data in the table above to plot the total energy as a function of the lattice constant. Fit a cubic polynomial to the data, and find the volume that minimizes the total energy.

Figure 27: Total energy vs. fcc lattice constant for Cu. It appears the minimum is near 3.65 Å.

If you want to know the lattice constant that gives the lowest energy, you would fit an [equation of state](#) to the data. Here is an example using `ase.utils.eos`. Note that this module only fits a cubic polynomial to the data. There are many other possibilities discussed in the appendix on [equations of state](#).

```

1  from jasp import *
2  from ase.utils.eos import EquationOfState
3  LC = [3.5, 3.55, 3.6, 3.65, 3.7, 3.75]
4  energies = []
5  volumes = []
6  for a in LC:
7      with jasp('bulk/Cu-{}'.format(a)) as calc:
8          atoms = calc.get_atoms()
9          volumes.append(atoms.get_volume())
10         energies.append(atoms.get_potential_energy())
11
12  eos = EquationOfState(volumes, energies)
13  v0, e0, B = eos.fit()
14
15  print '''
16  v0 = {} A^3
17  E0 = {} eV
18  B  = {} eV/A^3'''.format(v0, e0, B)
19
20  eos.plot('images/Cu-fcc-eos.png')
```

```

v0 = 12.0167118546 A^3
E0 = -3.7246811445 eV
B  = 0.859009528171 eV/A^3
```

Figure 28: Total energy vs. volume for fcc Cu with fitted cubic polynomial equation of state.

Before we jump into the bcc calculations, let us consider what range of lattice constants we should choose. The fcc lattice is close-packed, and the volume of the primitive cell is $V = 1/4a^3$ or about 11.8 Å³/atom. The volume of the equilibrium bcc primitive cell will probably be similar to that. The question is: what bcc lattice constant gives that volume? The simplest way to answer this is to compute the answer. We will make a bcc crystal at the fcc lattice constant, and then compute the scaling factor needed to make it the right volume.

```

1 from ase import Atom, Atoms
2 import numpy as np
3 a = 3.61 # lattice constant
4
5 atoms = Atoms([Atom('Cu', [0,0,0])],
6               cell=0.5 * a*np.array([[ 1.0,  1.0, -1.0],
7                                       [-1.0,  1.0,  1.0],
8                                       [ 1.0, -1.0,  1.0]]))
9
10 print 'BCC lattice constant = {0} Ang'.format(a*(11.8/atoms.get_volume())**(1./3.))

```

BCC lattice constant = 2.86838428403 Ang

Now we run the equation of state calculations.

```

1 from jasp import *
2 from ase import Atom, Atoms
3
4 LC = [2.75, 2.8, 2.85, 2.9, 2.95, 3.0]
5
6 for a in LC:
7     atoms = Atoms([Atom('Cu', [0,0,0])],
8                   cell=0.5 * a * np.array([[ 1.0,  1.0, -1.0],
9                                             [-1.0,  1.0,  1.0],
10                                            [ 1.0, -1.0,  1.0]]))
11
12     with jasp('bulk/Cu-bcc-{0}'.format(a),
13              xc='PBE',

```

```

14         encut=350,
15         kpts=(8,8,8),
16         atoms=atoms) as calc:
17     calc.calculate()

```

Finally, we will compare the two crystal structures.

```

1  from jasp import *
2
3  # bcc energies and volumes

36  print '|-'
37  for lc, e in zip(bcc_LC, bcc_energies):
38      print '| {} | {} |'.format(lc, e)

```

Table 3: Total energy vs. lattice constant for BCC Cu

Lattice constant (Å ³)	Total energy (eV)
2.75	-3.587523
2.8	-3.668112
2.85	-3.708699
2.9	-3.716496
2.95	-3.697781
3.0	-3.657913

Exercise 4.3

Use the data for FCC and BCC Cu to plot the total energy as a function of the lattice constant.

Figure 29: Comparison of energies between fcc and bcc Cu. The fcc structure is lower in energy.

Note we plot the energy vs. atomic volume. That is because the lattice constants of the two crystal structures are very different. It also shows that the atomic volumes in the two structures are similar.

What can we say here? The fcc structure has a lower energy than the bcc structure, so we can conclude the fcc structure is more favorable. In fact, the fcc structure is the experimentally found structure for Cu. Some caution is in order; if you run these calculations at a $4 \times 4 \times 4$ k -point grid, the bcc structure is more stable because the results are not converged!

Exercise 4.4

Compute the energy vs. volume for fcc and bcc Cu for different k -point grids. Determine when each result has converged, and which structure is more stable.

What can we say about the relative stability of fcc to hcp? Nothing, until we calculate the hcp equation of state.

4.2.2 hcp

The hcp lattice is more complicated than the fcc/bcc lattices because there are two lattice parameters: a and c or equivalently: a and c/a . We will start by making a grid of values and find the set of parameters that minimizes the energy. See Figure 30.

```
1 from ase.lattice.hexagonal import HexagonalClosedPacked
2 from jasp import *
```

```

3  import matplotlib.pyplot as plt
4
5  atoms = HexagonalClosedPacked(symbol='Ru',
6                                latticeconstant={'a':2.7, 'c/a':1.584})
7
8  a_list = [2.5, 2.6, 2.7, 2.8, 2.9]
9  covera_list = [1.4, 1.5, 1.6, 1.7, 1.8]
10
11 for a in a_list:
12     energies = []
13     for covera in covera_list:
14
15         atoms = HexagonalClosedPacked(symbol='Ru',
16                                         latticeconstant={'a':a, 'c/a':covera})
17
18         wd = 'bulk/Ru/{0:1.2f}--{1:1.2f}'.format(a,covera)
19
20         with jasp(wd,
21                   xc='PBE',
22                   kpts=(6, 6, 4), # the c-axis is longer than the a-axis, so we use fewer kpoints.
23                   encut=350,
24                   atoms=atoms) as calc:
25             try:
26                 energies.append(atoms.get_potential_energy())
27             except (VaspSubmitted, VaspQueued):
28                 pass
29     plt.plot(covera_list, energies, label='a={0}'.format(a))
30
31 plt.xlabel('$c/a$ ($\AA$)')
32 plt.ylabel('Energy (eV)')
33 plt.legend()
34 plt.savefig('images/Ru-covera-scan.png')

```

It looks like there is a minimum in the $a=2.7$ Å curve, at a c/a ratio of about 1.6. We can look at the same data in a contour plot which shows more clearly there is minimum in all directions near that point (Figure 31).

```

30 plt.ylabel('$c/a$')
31
32 plt.legend()
33 plt.savefig('images/ru-contourf.png')
34 plt.show()

```

4.2.3 Complex structures with internal degrees of freedom

A unit cell has six degrees of freedom: the lengths of each unit cell vector, and the angle between each vector. There may additionally be internal degrees of freedom for the atoms. It is impractical to try the approach used for the hcp Ru on anything complicated. Instead, we rely again on algorithms to optimize the unit cell shape, volume and internal degrees of freedom. It is usually not efficient to make a wild guess of the geometry and then turn VASP loose on to optimize it. Instead, the following algorithm works pretty well.

1. With the atoms frozen find the volume (at constant shape) that minimizes the total energy. The goal here is to just get an idea of where the right volume is.
2. Perform a set of calculations at constant volume around the minimum from step 1, but the shape is allowed to change (ISIF=4) and the atoms allowed to relax.

Figure 31: Contour plot of the total energy of hcp Ru for different values of a and c/a .

3. Finally, do a final calculation near the minimum energy allowing the volume to also change. (ISIF=3)

This multistep process is pretty reasonable to get a converged structure pretty quickly. We will illustrate the process on TiO_2 which has two lattice parameters and one internal degree of freedom.

```

1  # step 1 frozen atoms and shape at different volumes
2  from ase import Atom, Atoms
3  import numpy as np
4  from jasp import *
5  import matplotlib.pyplot as plt
6
7  '''
8  create a TiO2 structure from the lattice vectors at
9  http://cst-www.nrl.navy.mil/lattice/struk/c4.html
10  '''
11  a = 4.59 # experimental degrees of freedom.
12  c = 2.96
13  u = 0.3 #internal degree of freedom!
14
15  #primitive vectors
16  a1 = a*np.array([1.0, 0.0, 0.0])
17  a2 = a*np.array([0.0, 1.0, 0.0])
18  a3 = c*np.array([0.0, 0.0, 1.0])
19

```

```

20 atoms = Atoms([Atom('Ti', [0., 0., 0.]),
21               Atom('Ti', 0.5 * a1 + 0.5 * a2 + 0.5 * a3),
22               Atom('O', u * a1 + u * a2),
23               Atom('O', -u * a1 - u * a2),
24               Atom('O', (0.5 + u) * a1 + (0.5 - u) * a2 + 0.5 * a3),
25               Atom('O', (0.5 - u) * a1 + (0.5 + u) * a2 + 0.5 * a3)],

The spacegroup is (136)

The points to note here are the following:

1. The stress on the unit cell is very low.
2. The forces on the atoms are very small (less than 0.0 eV/Å).
3. The agreement with experimental lattice parameters is pretty good.
4. The spacegroup is still correct.

4.2.4 TODO the volume is very small (61) compared to what we expected (64) something may be wrong!

4.3 Effect of calculation parameters on bulk calculations

Several parameters affect the results in bulk calculations

4.3.1 TODO k-point convergence ?

4.3.2 Effect of SIGMA

In the self-consistent cycle of a DFT calculation, the total energy is minimized with respect to occupation of the Kohn-Sham orbitals. At absolute zero, a band is either occupied or empty. This discrete occupation results in discontinuous changes in energy with changes in occupation, which makes it difficult to converge. One solution is to artificially broaden the band occupancies, as if they were occupied at a higher temperature where partial occupation is possible. This results in a continuous dependence of energy on the partial occupancy, and dramatically increases the rate of convergence. SIGMA and ISMEAR affect how the partial occupancies of the bands are determined.

Some rules to keep in mind:

1. The smearing methods were designed for metals. For molecules, semiconductors and insulators you should use a very small SIGMA (e.g. 0.01).
2. Standard values for metallic systems is SIGMA=0.1, but the best SIGMA may be material specific.

The consequence of this finite temperature is that additional bands must be included in the calculation to allow for the partially occupied states above the Fermi level; the number of extra bands depends on the temperature used. An example of the maximum occupancies of the bands for an Al(111) slab as a function of the Fermi temperature is shown in Figure 34. Obviously, as the Fermi temperature approaches 0 K, the occupancy approaches a step function. It is preferable that the occupancy of several of the highest bands be zero (or at least of order 1×10^{-8}) to ensure enough variational freedom was available in the calculation. Consequently, it is suggested that fifteen to twenty extra bands be used for a Fermi temperature of $k_b T = 0.20$ eV, or that the Fermi temperature be decreased to $k_b T = 0.10$ eV. In any case, it should be determined that enough bands were used by examination of the occupancies. It is undesirable to have too many extra bands, as this will add computational time.

Below we show the effect of SIGMA on the band occupancies.

```

Figure 34: Effects of SIGMA on the occupancies of the Cu system.

4.4 Cohesive energy

The cohesive energy is defined as the energy to separate neutral atoms in their ground electronic state from the solid at 0K at 1 atm. We will compute this for rhodium. Rh is normally an fcc metal, so we will use that structure and let VASP find the equilibrium volume for us.

```

1  from jasp import *
2  from ase.lattice.cubic import FaceCenteredCubic
3  from ase import Atoms, Atom
4  # bulk system
5  atoms = FaceCenteredCubic(directions=[[0,1,1],
6                                     [1,0,1],
7                                     [1,1,0]],
8                             size=(1,1,1),
9                             symbol='Rh')
10
11  with jasp('bulk/bulk-rh',
12            xc='PBE',
13            encut=350,
14            kpts=(4,4,4),
15            isif=3,
16            ibrion=2,
17            nsw=10,
18            atoms=atoms) as calc:
19      bulk_energy = atoms.get_potential_energy()
20
21  # atomic system
22  atoms = Atoms([Atom('Rh',[5, 5, 5])],
23               cell=(7, 8, 9))
24
25  with jasp('bulk/atomic-rh',
26            xc='PBE',
27            encut=350,
28            kpts=(1, 1, 1),
29            atoms=atoms) as calc:

```

```

30     atomic_energy = atoms.get_potential_energy()
31
32     cohesive_energy = atomic_energy - bulk_energy
33     print 'The cohesive energy is {0:1.3f} eV'.format(cohesive_energy)

```

The cohesive energy is 6.187 eV

According to Kittel, the cohesive energy of Rh is 5.75 eV. There are a few reasons we may have discrepancy here:

1. The k-point grid used in the bulk state is not very dense. However, you can see below that the total energy is pretty converged by a $6 \times 6 \times 6$ k -point grid.
2. We did not check for convergence with the planewave cutoff.
3. We neglected spin on the atomic state. Rh in the atomic state has this electronic structure: [Kr] 4d8 5s1 and is a doublet.

First we consider the k-point convergence.

```

1  from jasp import *
2
3  with jasp('bulk/atomic-rh') as calc:
4      atoms = calc.get_atoms()
5      atomic_energy = atoms.get_potential_energy()
6
7  with jasp('bulk/bulk-rh') as calc:
8      atoms = calc.get_atoms()
9
10 kpts = [3, 4, 6, 9, 12, 15, 18]
11
12 for k in kpts:
13     with jasp('bulk/bulk-rh-kpts-{0}'.format(k),
14             xc='PBE',
15             encut=350,
16             kpts=(k,k,k),
17             atoms=atoms) as calc:
18         e = atoms.get_potential_energy()
19
20     print '{0:2d}, {0:2d}, {0:2d}: cohesive energy = {1} eV'.format(k,e-atomic_energy)

```

```

( 3,  3,  3): cohesive energy = -4.837472 eV
( 4,  4,  4): cohesive energy = -6.189573 eV
( 6,  6,  6): cohesive energy = -6.210668 eV
( 9,  9,  9): cohesive energy = -6.208576 eV
(12, 12, 12): cohesive energy = -6.215367 eV
(15, 15, 15): cohesive energy = -6.215319 eV
(18, 18, 18): cohesive energy = -6.216032 eV

```

Using only 1 k-point for the bulk energy is a terrible approximation! It takes at least a 6×6 grid to get the total energy converged to less than 10 meV. Note we do not need to check the k-point convergence of the atomic state because it is surrounded by vacuum on all sides, and so there should not be any dispersion in the bands.

We will examine the magnetic state next.

```

1  from jasp import *
2  from ase.lattice.cubic import FaceCenteredCubic
3  from ase import Atoms, Atom
4  # bulk system
5  atoms = FaceCenteredCubic(directions=[[0,1,1],
6                                     [1,0,1],
7                                     [1,1,0]],
8                             size=(1,1,1),
9                             symbol='Rh')
10
11 with jasp('bulk/bulk-rh',
12          xc='PBE',
13          encut=350,
14          kpts=(4,4,4),
15          isif=3,
16          ibrion=2,
17          nsw=10,
18          atoms=atoms) as calc:
19     bulk_energy = atoms.get_potential_energy()
20
21 # atomic system
22 atoms = Atoms([Atom('Rh',[5,5,5],magmom=1)],
23              cell=(7,8,9))
24
25 with jasp('bulk/atomic-rh-sp',
26          xc='PBE',
27          encut=350,
28          kpts=(1,1,1),
29          ispin=2,
30          atoms=atoms) as calc:
31     atomic_energy = atoms.get_potential_energy()
32
33 cohesive_energy = atomic_energy - bulk_energy
34 print 'The cohesive energy is {0:1.3f} eV'.format(cohesive_energy)

```

The cohesive energy is 5.887 eV

Again, the value in Kittel³ is 5.75 eV which is very close to this value. Finally, it is also possible there is a lower energy non-spherical atom energy; we did not check that at all (see [Estimating triplet oxygen dissociation energy with low symmetry](#)).

4.5 Effect of pressure on phase stability

So far we have only considered relative stability at a pressure of 0 Pa. We now consider the relative stability of two phases under pressure. We will consider TiO₂ in the rutile and anatase phases.

The pressure is defined by: $P = -\left(\frac{\partial E}{\partial V}\right)_T$. So if we have an equation of state $E(V)$ we can calculate the pressure at any volume, or alternatively, given a pressure, compute the volume. Pressure can affect the energy of two phases differently, so that one may become stable under pressure. The condition where a phase transition occurs is when the pressure in the two phases is the same, which occurs at a common tangent.

To show this, we need $E_{\text{rutile}}(V)$ and $E_{\text{anatase}}(V)$.

```

```

Figure 35: Equations of state ($E(V)$) for anatase and rutile TiO_2 .

To find the conditions where a phase transition occurs, we have to find the common tangent

line between the rutile and anatase phases. In other words we have to solve these two equations:

$$(E_{\text{anatase}}(V1) - E_{\text{rutile}}(V2))/(V1 - V2) = P_{\text{anatase}}(V1)$$

$$(E_{\text{anatase}}(V1) - E_{\text{rutile}}(V2))/(V1 - V2) = P_{\text{rutile}}(V2)$$

This is a nonlinear algebra problem. We use the `scipy.optimize.fsolve` to solve this problem.

38              polyval(anatase_epars,x0[1])], 'ko-', label='common tangent')
39 plt.legend()
40 plt.xlabel('Volume ($\AA^3$/f.u.)')
41 plt.ylabel('Total energy (eV/f.u.)')
42 plt.savefig('images/eos-common-tangent.png')

```

The solutions are at V = [31.67490656 34.60893508]

Anatase pressure: 4.52495142656 GPa

Rutile pressure: 4.5249514267 GPa

At a pressure of 4.5 GPa, we expect that anatase will start converting into rutile. Along this common tangent, a mixture of the two phases will be more stable than either pure phase.

Figure 36: Illustration of the common tangent that shows the pressure where anatase and rutile coexist before anatase converts to rutile.

4.6 Bulk reaction energies

4.6.1 Alloy formation energies

In this section we will consider how to calculate the formation energy of an fcc Cu-Pd alloy and how to use that information to discuss relative stabilities. First, we compute the bulk energies of fcc Cu and fcc Pd.

Basic alloy formation energy

```

1  # get bulk Cu and Pd energies.
2  from jasp import *
3
4  from ase import Atom, Atoms
5
6  atoms = Atoms([Atom('Cu', [0.000, 0.000, 0.000])],
7                cell= [[ 1.818, 0.000, 1.818],
8                      [ 1.818, 1.818, 0.000],
9                      [ 0.000, 1.818, 1.818]])
10
11  with jasp('bulk/alloy/cu',
12           xc='PBE',
13           encut=350,
14           kpts=(13,13,13),
15           nbands=9,
16           ibrion=2,
17           isif=4,
18           nsw=10,
19           atoms=atoms) as calc:
20      cu = atoms.get_potential_energy()
21
22  atoms = Atoms([Atom('Pd', [0.000, 0.000, 0.000])],

```

```

23         cell=[[ 1.978,  0.000,  1.978],
24               [ 1.978,  1.978,  0.000],
25               [0.000,  1.978,  1.978]])
26
27     with jasp('bulk/alloy/pd',
28               xc='PBE',
29               encut=350,
30               kpts=(13,13,13),
31               nbands=9,
32               ibrion=2,
33               isif=4,
34               nsw=10,
35               atoms=atoms) as calc:
36         pd = atoms.get_potential_energy()
37
38     print 'Cu energy = {0} eV'.format(cu)
39     print 'Pd energy = {0} eV'.format(pd)

```

Cu energy = -3.723305 eV
 Pd energy = -5.183823 eV

Note that the Pd energy is more negative than the Cu energy. This does not mean anything significant. We cannot say Pd is more stable than Cu; it is not like Cu could transmute into Pd!

```

1  from jasp import *
2  from ase import Atom, Atoms
3
4  atoms = Atoms([Atom('Cu', [0.000, 0.000, 0.000]),
5                  Atom('Pd', [-1.652, 0.000, 2.039])],
6                cell=[[ 0.000, -2.039, 2.039],
7                      [ 0.000, 2.039, 2.039],
8                      [-3.303, 0.000, 0.000]])
9
10     with jasp('bulk/alloy/cupd-1',
11               xc='PBE',
12               encut=350,
13               kpts=(12,12,8),
14               nbands=17,
15               ibrion=2,
16               isif=4,
17               nsw=10,
18               atoms=atoms) as calc:
19         cupd1 = atoms.get_potential_energy()
20
21
22     atoms = Atoms([Atom('Cu', [-0.049, 0.049, 0.049]),
23                     Atom('Cu', [-11.170, 11.170, 11.170]),
24                     Atom('Pd', [-7.415, 7.415, 7.415]),
25                     Atom('Pd', [-3.804, 3.804, 3.804])],
26                   cell=[[-5.629, 3.701, 5.629 ],
27                         [-3.701, 5.629, 5.629 ],
28                         [-5.629, 5.629, 3.701 ]])
29
30     with jasp('bulk/alloy/cupd-2',
31               xc='PBE',
32               encut=350,
33               kpts=(8,8,8),
34               nbands=34,
35               ibrion=2,
36               isif=4,
37               nsw=10,

```

```

38         atoms=atoms) as calc:
39     cupd2 = atoms.get_potential_energy()
40
41     print 'cupd-1 = {0} eV'.format(cupd1)
42     print 'cupd-2 = {0} eV'.format(cupd2)

```

```

cupd-1 = -9.147752 eV
cupd-2 = -17.97924 eV

```

Looking at these energies, you could be tempted to say cupd-2 is more stable than cupd-1 because its energy is much lower. This is wrong, however, because cupd-2 has twice as many atoms as cupd-1. We should compare the normalized total energies.

```

1  from jasp import *
2
3  with jasp('bulk/alloy/cupd-1') as calc:
4      atoms = calc.get_atoms()
5      e1 = atoms.get_potential_energy()/len(atoms)
6
7  with jasp('bulk/alloy/cupd-2') as calc:
8      atoms = calc.get_atoms()
9      e2 = atoms.get_potential_energy()/len(atoms)
10
11     print 'cupd-1: {0} eV/atom'.format(e1)
12     print 'cupd-2: {0} eV/atom'.format(e2)

```

```

cupd-1: -4.573876 eV/atom
cupd-2: -4.49481 eV/atom

```

After normalizing by number of atoms, we can see that cupd-1 is a more stable structure. However, we are looking at total energies, and we might ask: is cupd-1 more stable than an unreacted mixture of the parent compounds, fcc Cu and Pd? In other words, is the following reaction exothermic:

$2\text{Cu} + 2\text{Pd} \rightarrow \text{Cu}_2\text{Pd}_2$ for the two configurations we examined? Below, we show some pretty general code that computes these formation energies, and normalizes them by the number of atoms in the unit cell.

```

1  from jasp import *
2
3  with jasp('bulk/alloy/cu') as calc:
4      atoms = calc.get_atoms()
5      cu = atoms.get_potential_energy()/len(atoms)
6
7  with jasp('bulk/alloy/pd') as calc:
8      atoms = calc.get_atoms()
9      pd = atoms.get_potential_energy()/len(atoms)
10
11  with jasp('bulk/alloy/cupd-1') as calc:
12      atoms = calc.get_atoms()
13      e1 = atoms.get_potential_energy()
14      for atom in atoms:
15          if atom.symbol == 'Cu':
16              e1 -= cu
17          else:
18              e1 -= pd
19      e1 /= len(atoms)

```

```

20
21 with jasp('bulk/alloy/cupd-2') as calc:
22     atoms = calc.get_atoms()
23     e2 = atoms.get_potential_energy()
24     for atom in atoms:
25         if atom.symbol == 'Cu':
26             e2 -= cu
27         else:
28             e2 -= pd
29     e2 /= len(atoms)
30
31 print 'Delta Hf cupd-1 = {0:1.2f} eV/atom'.format(e1)
32 print 'Delta Hf cupd-2 = {0:1.2f} eV/atom'.format(e2)

```

Delta Hf cupd-1 = -0.12 eV/atom
Delta Hf cupd-2 = -0.04 eV/atom

The answer is yes. Both structures are energetically more favorable than an equal composition mixture of the parent metals. The heat of formation for both structures is exothermic, but the cupd-1 structure is more stable than the cupd-2 structure. This is shown conceptually in Figure 37.

Figure 37: Conceptual picture of two alloys with exothermic formation energies. The dashed line represents a composition weighted average energy of the parent metals. E4 and E3 are energies associated with two different alloy structures at the same composition. Both structures are more stable than a mixture of pure metals with the same composition, but E3 is more stable than E4.

We will now examine another structure at another composition and its stability.

```

1  from jasp import *
2  from ase import Atom, Atoms
3
4  # parent metals
5  with jasp('bulk/alloy/cu') as calc:
6      atoms = calc.get_atoms()
7      cu = atoms.get_potential_energy()/len(atoms)
8
9  with jasp('bulk/alloy/pd') as calc:
10     atoms = calc.get_atoms()
11     pd = atoms.get_potential_energy()/len(atoms)
12
13  atoms = Atoms([Atom('Cu', [-3.672, 3.672, 3.672]),
14                Atom('Cu', [0.000, 0.000, 0.000]),
15                Atom('Cu', [-10.821, 10.821, 10.821]),
16                Atom('Pd', [-7.246, 7.246, 7.246])],
17                cell=[[-5.464, 3.565, 5.464],
18                    [-3.565, 5.464, 5.464],
19                    [-5.464, 5.464, 3.565]])
20
21  with jasp('bulk/alloy/cu3pd-1',
22            xc='PBE',
23            encut=350,
24            kpts=(8,8,8),
25            nbands=34,
26            ibrion=2,
27            isif=4,
28            nsw=10,
29            atoms=atoms) as calc:
30      e3 = atoms.get_potential_energy()
31      for atom in atoms:
32          if atom.symbol == 'Cu':
33              e3 -= cu
34          else:
35              e3 -= pd
36      e3 /= len(atoms)
37  print 'Delta Hf cu3pd-1 = {0:1.2f} eV/atom'.format(e3)

```

Delta Hf cu3pd-1 = -0.02 eV/atom

The formation energy is slightly exothermic, which means the structure is more stable than a mixture of the parent metals. However, let us consider whether the structure is stable with respect to phase separation into pure Cu and the cupd-1 structure. We define the following quantities:

$$H_{f,Cu} = 0.0 \text{ eV/atom}, x_0 = 0, H_{f,cupd-1} = -0.12 \text{ eV/atom}, x_3 = 0.5.$$

The composition weighted average at $x_{Pd} = 0.25$ is:

$$H_f = H_{f,Cu} + \frac{x_0 - x}{x_0 - x_3} (H_{f,cupd-1} - H_{f,Cu})$$

```

1  x0 = 0.0; x3 = 0.5; x = 0.25;
2  Hf1 = 0.0; Hf3 = -0.12;
3
4  print 'Composition weighted average = {0} eV'.format(Hf1 + (x0-x)/(x0-x3)*(Hf3 - Hf1))

```

Composition weighted average = -0.06 eV

We find the weighted composition formation energy of pure Cu and cupd-1 is more favorable than the formation energy of cu3pd-1. Therefore, we could expect that structure to phase separate into a mixture of pure Cu and cupd-1. Schematically what we are seeing is shown in Figure 38.

Figure 38: Illustration of of an alloy structure with an exothermic formation energy that is not stable with respect to phase separation. The solid line shows the composition weighted average energy of a mixture of Cu and cupd-2. Since the energy of cu3pd-1 is above the solid line, it is less favorable than a mixture of Cu and cupd-2 with the same composition.

Finally, let us consider one more structure with the Cu_3Pd stoichiometry.

```

1  from jasp import *
2  from ase import Atom, Atoms
3
4  # parent metals
5  with jasp('bulk/alloy/cu') as calc:
6      atoms = calc.get_atoms()
7      cu = atoms.get_potential_energy()/len(atoms)
8
9  with jasp('bulk/alloy/pd') as calc:
10     atoms = calc.get_atoms()
11     pd = atoms.get_potential_energy()/len(atoms)
12
13  atoms = Atoms([Atom('Cu', [-1.867, 1.867, 0.000]),
14                Atom('Cu', [0.000, 0.000, 0.000]),

```

```

15         Atom('Cu', [0.000, 1.867, 1.867]),
16         Atom('Pd', [-1.867, 0.000, 1.867]),
17         cell=[[-3.735, 0.000, 0.000],
18               [0.000, 0.000, 3.735],
19               [0.000, 3.735, 0.000]])
20
21 with jasp('bulk/alloy/cu3pd-2',
22          xc='PBE',
23          encut=350,
24          kpts=(8,8,8),
25          nbands=34,
26          ibrion=2,
27          isif=4,
28          nsw=10,
29          atoms=atoms) as calc:
30     e4 = atoms.get_potential_energy()
31     for atom in atoms:
32         if atom.symbol == 'Cu':
33             e4 -= cu
34         else:
35             e4 -= pd
36     e4 /= len(atoms)
37 print 'Delta Hf cu3pd-2 = {0:1.2f} eV/atom'.format(e4)

```

Delta Hf cu3pd-2 = -0.10 eV/atom

This looks promising: the formation energy is much more favorable than cu3pd-1, and it is below the composition weighted formation energy of -0.06 eV/atom. Consequently, we conclude that this structure will not phase separate into a mixture of Cu and CuPd. We cannot say, however, if there is a more stable phase not yet considered, or if it might phase separate into two other phases. We also note here that we have ignored a few other contributions to alloy stability. We have only considered the electronic energy contributions to the formation energy. At temperatures above absolute zero there are additional contributions including configurational and vibrational entropy, which may stabilize some structures more than others. Finally, our analysis is limited to comparisons of the structures computed on the fcc lattice. In fact, it is known that the CuPd alloy forms a bcc structure. We did not calculate that structure, so we can not say if it is more or less stable than the obvious fcc structure we found.

Figure 39: Illustration that cu3pd-2 is more stable than cu3pd-1 and that it is more stable than a composition weighted mixture of Cu and cupd-1. The dotted line shows the energy of a composition weighted average energy of a mixture of Cu and cupd-1. Since cu3pd-2 is below the dotted line, it is more stable than the phase-separated mixture.

The construction of alloy phase diagrams is difficult. You are always faced with the possibility that there is a phase that you have not calculated that is more stable than the ones you did calculate. One approach is to use a tool that automates the discovery of relevant structures such as the Alloy Theoretic Automated Toolkit (ATAT)^{46;47} which uses a cluster expansion methodology.

4.6.2 Metal oxide oxidation energies

We will consider here the reaction $2 \text{Cu}_2\text{O} + \text{O}_2 \rightleftharpoons 4 \text{CuO}$. The reaction energy is:

$$\Delta E = 4E_{\text{CuO}} - 2E_{\text{Cu}_2\text{O}} - E_{\text{O}_2}.$$

We need to compute the energy of each species.

Cu₂O calculation

```

1 # run Cu2O calculation
2 from jasp import *

Reaction energy = -1.966168 eV

There are a few reasons why our number does not agree with the experimental reaction energy. One reason is related to errors in the O₂ dissociation energy, and another reason is related to localization of electrons in the Cu 3d orbitals.⁴⁸ The first error of incorrect O₂ dissociation error is a systematic error that can be corrected empirically.⁴⁸ Fixing the second error requires the application of DFT+U (see [DFT+U](#))

4.7 Bulk density of states

The density of states refers to the number of electronic states in a particular energy range.

The solution to Eq. (1) yields a set of Kohn-Sham (K-S) orbitals and an associated set of eigenvalues that correspond to the energies of these orbitals, neither of which have any known directly observable meaning.¹⁷ The sum of the squared K-S orbitals, however, is equal to the electron density (Eq. (3)), and the sum of the eigenvalues is a significant part of the total energy (Eq. (4)). Thus, it seems reasonable to suppose these quantities have other significant relationships to physical observables. Perdew et al. showed that the highest occupied eigenvalue is equal to the ionization energy of a system within an exact density functional theory,²³ but their interpretation has been vigorously debated in the literature,^{49–51} and is only true for the exact exchange/correlation functional, not the approximate ones used in practice² Section 5.3.3. Stowasser and Hoffmann discussed an approach to using the K-S orbitals in more traditional molecular orbital interpretations, but the results were primarily qualitative.⁵² More recently, a DFT analog of Koopmans' theorem has been developed that formally identifies the eigenvalues with vertical ionization potentials, which can be measured with photoelectron spectroscopy.⁵³

Despite the arguments against ascribing physical meaning to the K-S orbitals and eigenvalues, it has become fairly standard, especially for solids, to use them to calculate the density of states (DOS)⁵⁴ Sec. VI. B. This has been found to yield reasonable results for the valence bands in metals, but poor results for tightly bound orbitals and band gaps.²³ A highly technical discussion of this issue can be found in Ref.⁵⁵. The density of states can be calculated by a sum over the k-points:¹⁴

$$\rho(\epsilon) = \sum_{\mathbf{k}} \omega_{\mathbf{k}} \sum_i \beta(\epsilon - \epsilon_{i\mathbf{k}}) \quad (7)$$

where $\omega_{\mathbf{k}}$ is the weight associated with the k-point, and β is a broadening function, typically a gaussian function, to account for the finite number of k-points used in the calculations. The amount of broadening is arbitrary, and should tend to zero as the number of k-points approaches infinity.

17 plt.plot(e, d)
18 plt.xlabel('energy [eV]')
19 plt.ylabel('DOS')
20 plt.savefig('images/pd-dos-ismear-5.png')

```

Figure 41: Total DOS for Pd computed with ISMEAR=-5

This is not that different from the regular ISMEAR, so I am not sure this is correct. Maybe there is another way to compute DOS when the tetrahedral method is used? This looks like the eigenvalue spectrum.

4.8 Atom projected density of states

One major disadvantage of a planewave basis set is that it is difficult to relate the completely delocalized planewaves to localized phenomena such as bonding. Much insight into bonding has been gained by atomic/molecular orbital theory, which has carried over to the solid-state

arena.⁶ Consequently, several schemes have been developed to project the one-electron Kohn-Sham wave functions onto atomic wave functions.^{56–58} In VASP, the one electron wave functions can be projected onto spherical harmonic orbitals. The radial component of the atomic orbitals extends to infinity. In a solid, this means that the projection on one atom may overlap with the projection on a neighboring atom, resulting in double counting of electrons. Consequently, a cutoff radius was introduced, beyond which no contributions are included. It is not obvious what the best cutoff radius is. If the radius is too small, it might not capture all of the electrons associated with the atom. However, if it is too large, it may include electrons from neighboring atoms. One might want to use different cutoff radii for different atoms, which have different sizes. Furthermore, the ideal cutoff radius for an atom may change in different environments, thus it would require an iterative procedure to determine it. This difficulty arises because the orbital-band occupations are not observable, thus how the electrons are divided up between atoms is arbitrary and, as will be seen later, is sensitive to the cutoff radius (and in other DFT implementations, the basis set). However, Mulliken orbital populations have been used successfully for many years to examine the qualitative differences between similar systems, and that is precisely what these quantities are used for here. Thus, a discussion of the analysis and results is warranted.

The *s* and *p* states in a metal are typically delocalized in space and more like free-electrons, whereas the *d*-orbitals are fairly localized in space and have been treated successfully with tight-binding theories such as extended Hückel theory,⁶ and linear muffin tin orbital theory.⁵⁹ Consequently, the remaining discussion will be focused on the properties of the projected *d*-states.

In this example, we consider how to get the atom-projected density of states (ADOS). We are interested in properties of the *d*-band on Pd, such as the *d*-band center and *d*-band width. You must set the **RWIGS** tag to get ADOS, and these are the Wigner-Seitz radii for each atom. By integrating the projected *d*-band up to the Fermi level, the *d*-band filling can be determined. It is not obvious what the electron count in the *d*-band should be for an atom in a metal. For a gas-phase, neutral metal atom in the ground state, however, the *d*-orbital electron count is well defined, so it will be used as an initial reference point for comparison.³

A powerful method for characterizing distributions is to examine various moments of the distribution (see Chapter 4 in Ref.⁶⁰ and Chapter 6 in Refs.⁶¹ and⁶²). The n^{th} order moment, μ_n , of a distribution of states $\rho(\epsilon)$ with respect to a reference ϵ_o is defined by

$$\mu_n = \frac{\int_{-\infty}^{\infty} \epsilon^n \rho(\epsilon - \epsilon_o) d\epsilon}{\int_{-\infty}^{\infty} \rho(\epsilon - \epsilon_o) d\epsilon} \quad (8)$$

In this work, the reference energy is always the Fermi level. The zeroth moment is just the total number of states, in this case it will be normalized to unity. The first moment is the average energy of distribution, analogous to the center of mass for a mass density distribution. The second moment is the mean squared width of the distribution. The third moment is a measure of skewness and the fourth moment is related to kurtosis, but these moments are rarely used, and only the first and second moments are considered in this work.

It is important to note that these projected density of states are not physical observables. They are the wavefunctions projected onto atomic orbitals. For some situations this makes sense, e.g. the *d* orbitals are fairly localized and reasonably approximated by atomic orbitals. The *s* valence orbitals in a metal, in contrast, are almost totally delocalized. Depending on the cutoff radius (RWIGS) you choose, you can see very different ADOS.

4.9 Band structures

To compute a band structure we do two things. First, we compute the self-consistent band structure. Then we compute the band structure at the desired k -points. We will use Si as an example (adapted from <http://bbs.sciencenet.cn/bbs/upload/20083418325986.pdf>).

```

1  from jasp import *
2  from ase import Atom, Atoms
3  from ase.visualize import view
4
5  a = 5.38936
6  atoms = Atoms([Atom('Si',[0,0,0]),
7                  Atom('Si',[0.25, 0.25, 0.25])])
8
9  atoms.set_cell([[a/2., a/2., 0.0],
10                 [0.0, a/2., a/2.],
11                 [a/2., 0.0, a/2.]],scale_atoms=True)
12
13  with jasp('bulk/Si-selfconsistent',
14            xc='PBE',
15            prec='Medium',
16            istsart=0,
17            icharg=2,
18            ediff=0.1e-03,
19            kpts=(4,4,4),
20            atoms=atoms) as calc:
21      calc.calculate()

```

Now, we run a new calculation along the k-point path desired. The standard VASP way of doing this is to modify the INCAR and KPOINTS file and rerun VASP. We will not do that. Doing that results in some lost information if you overwrite the old files. We will copy the old directory to a new directory, using code to ensure this only happens one time.

```

1  from jasp import *
2
3  wd = 'bulk/Si-bandstructure'
4
5  with jasp('bulk/Si-selfconsistent') as calc:
6      calc.clone(wd)
7
8  kpts = [[0.5,0.5,0.0], # L
9          [0,0,0],      # Gamma
10         [0,0,0],
11         [0.5, 0.5, 0.5]] # X
12
13  with jasp(wd,
14            kpts=kpts,
15            reciprocal=True,
16            kpts_nintersections=10,
17            icharg=11) as calc:
18      calc.calculate()

```

`jasp` does not have a fancy way of extracting band structures yet, so we will learn how to manually parse the EIGENVAL file here to generate the band structure.

```

1  f = open('bulk/Si-bandstructure/EIGENVAL', 'r')

```

Figure 46: Total energy vs. total magnetic moment for bcc Fe.

You can see here there is a minimum in energy at a total magnetic moment somewhere between 4 and 5. There are two Fe atoms in the unit cell, which means the magnetic moment on each atom must be about 2.5 Bohr-magnetons. This is a good guess for a real calculation. Note that VASP [recommends](#) you overestimate the magnetic moment guesses if you are looking for ferromagnetic solutions.

```

1  from jasp import *
2  from ase.lattice.cubic import BodyCenteredCubic
3
4

```

4.10.2 Antiferromagnetic spin states

In an antiferromagnetic material, there are equal numbers of spin up and down electrons that align in a regular pattern, but pointing in opposite directions so that there is no net magnetism. It is possible to model this by setting the magnetic moments on each `ase.Atom` object.

```

1  from jasp import *
2  from ase import Atom, Atoms
3
4  atoms = Atoms([Atom('Fe', [0.00, 0.00, 0.00], magmom=5),
5                Atom('Fe', [4.3, 4.3, 4.3], magmom=-5),
6                Atom('O', [2.15, 2.15, 2.15], magmom=0),
7                Atom('O', [6.45, 6.45, 6.45], magmom=0)],
8                cell=[[4.3, 2.15, 2.15],
9                     [2.15, 4.3, 2.15],
10                    [2.15, 2.15, 4.3]])
11
12 with jasp('bulk/afm-feo',
13          encut=350,
14          prec='Normal',
15          ispin=2,
16          nupdown=0, # this forces a non-magnetic solution
17          lorbit=11,
18          lreal=False,
19          atoms=atoms) as calc:
20     print 'Magnetic moments = ', atoms.get_magnetic_moments()
21     print 'Total magnetic moment = ', atoms.get_magnetic_moment()

```

```
Magnetic moments = [ 2.652 -2.652  0.    0.  ]
Total magnetic moment = 0.0
```

You can see that even though the total magnetic moment is 0, there is a spin on both Fe atoms, and they are pointing in opposite directions. Hence, the sum of spins is zero, and this arrangement is called anti-ferromagnetic.

5 Surfaces

5.1 Surface structures

As with molecules and bulk systems `ase` provides several convenience functions for making surfaces.

5.1.1 Simple surfaces

`ase` provides many [utility functions](#) to setup surfaces. Here is a simple example of an fcc111 Al surface. There are built in functions for fcc111, bcc110, bcc111, hcp001 and diamond111.

```
1 from ase.lattice.surface import fcc111
2 from ase.io import write
3
4 slab = fcc111('Al', size=(2,2,3), vacuum=10.0)
5
6 write('images/Al-slab.png', slab, rotation='90x', show_unit_cell=2)
```

None

Figure 47: An Al(111) slab with three layers and 20 Å of vacuum.

5.1.2 Vicinal surfaces

The vast majority of surface calculations are performed on flat surfaces. This is partially because these surfaces tend to have the lowest surface energies, and thus are likely to be experimentally observed. The flat surfaces, also known as low Miller index surfaces, also have small unit cells,

which tends to make them computationally affordable. There are, however, many reasons to model the properties of surfaces that are not flat. You may be interested in the reactivity of a step edge, for example, or you may use the lower coordination of steps as a proxy for nanoparticle reactivity. Many stepped surfaces are not that difficult to make now. The main idea in generating them is described [here](#). `ase` provides a general function for making vicinal surfaces. Here is an example of a (211) surface.

```
1 from ase.lattice.surface import surface
2 from ase.io import write
3
4 # Au(211) with 9 layers
5 s1 = surface('Au', (2, 1, 1), 9)
6 s1.center(vacuum=10, axis=2)
7
8 write('images/Au-211.png',
9       s1.repeat((3,3,1)),
10      rotation='-30z,90x', # change the orientation for viewing
11      show_unit_cell=2)
```

None

Figure 48: An Au(211) surface constructed with ase.

5.2 Surface relaxation

When a surface is created, the bulk symmetry is broken and consequently there will be forces on the surface atoms. We will examine some consequences of this with a simple Al slab. First, we show there are forces on the slab atoms.

```
1 from jasp import *
2 from ase.lattice.surface import fcc111
3
4 atoms = fcc111('Al', size=(1,1,4), vacuum=10.0)
5
6 with jasp('surfaces/Al-slab-unrelaxed',
7           xc='PBE',
8           kpts=(6,6,1),
9           encut=350,
10          atoms=atoms) as calc:
11     atoms.get_forces()
12     print calc
```

```

```
1 deltaz = 2.33826859022 angstroms
2 deltaz = 2.33826859022 angstroms
3 deltaz = 2.33826859022 angstroms
```

We have to make some decisions about how to relax the slab. One choice would be to relax all the atoms in the slab. If we do that, then there will be no atoms with bulk like spacing unless we increase the slab thickness pretty dramatically. It is pretty common to freeze some atoms at the bulk coordinates, and let the others relax. We will freeze the bottom two layers (defined by tags 3 and 4) and let the first two layers relax. To do that we add constraints to the slab.

Note: the [ase.constraints](#) are only partially used by jasp. The `ase.constraints.FixAtoms` constraint gets written to the POSCAR file, and is then used internally in Vasp. The only other constraint that VASP can use internally is `ase.constraints.FixScaled`. The other constraints are not written to the POSCAR and are not used by VASP.

```

```

You can see that atoms 2 and 3 (the ones we relaxed) now have very low forces on them and it appears that atoms 0 and 1 have no forces on them. That is because the FixAtoms constraint works by setting the forces on those atoms to zero. We can see in the next example that the z-positions of the relaxed atoms have indeed relaxed and changed, while the position of the frozen atoms did not change.

```

d_(3,2) = 2.34530960922 angstroms

```

5.3 Surface reconstruction

We previously considered how relaxation can lower the surface energy. For some surfaces, a more extreme effect can reduce the surface energy: reconstruction. In a simple surface relaxation, the basic structure of a surface is preserved. However, sometimes there is a different surface structure that may have a lower surface energy.

TODO: some citations for famous reconstructions Si- $\sqrt{7} \times \sqrt{7}$ Pt(100) hex reconstruction Au(111) herringbone reconstruction

We will consider the (110) missing row reconstruction.⁶⁶ For some metals, especially Pt and Au, it is energetically favorable to form the so-called missing row reconstruction where every other row in the surface is “missing”. It is favorable because it lowers the surface energy. Let us consider how we might calculate and predict that. It is straightforward to compute the energy of a (110) slab, and of a (110) slab with one row missing. However, these slabs contain different numbers of atoms, so we cannot directly compare the total energies to determine which energy is lower.

We have to consider where the missing row atoms have gone, so we can account for their energy. We will consider that they have gone into the bulk, and so we to consider the energy associated with the following transformation:

slab₁₁₀ → slab_{missingrow} + bulk

Thus, if this change in energy: $E_{\text{bulk}} + E_{\text{slab}_{\text{missingrow}}} - E_{\text{slab}_{110}}$ is negative, then the formation of the missing row is expected to be favorable.

5.3.1 Au(110) missing row reconstruction

We first consider the Au(110) case, where the reconstruction is known to be favorable.

Clean Au(110) slab

```

Analysis of energies

```

1 from jasp import *
2
3 with jasp('surfaces/Au-110') as calc:
4     slab = calc.get_atoms()
5     eslab = slab.get_potential_energy()
6
7 with jasp('surfaces/Au-110-missing-row') as calc:
8     missingrow = calc.get_atoms()
9     emissingrow = missingrow.get_potential_energy()
10
11 with jasp('bulk/Au-fcc') as calc:
12     bulk = calc.get_atoms()
13     ebulk = bulk.get_potential_energy()
14
15 print 'natoms slab          = {}'.format(len(slab))
16 print 'natoms missing row = {}'.format(len(missingrow))
17 print 'natoms bulk         = {}'.format(len(bulk))
18
19 print 'dE = {:.3f} eV'.format(emissingrow + ebulk - eslab)

```

```

natoms slab          = 12
natoms missing row = 11
natoms bulk         = 1
dE = -0.070 eV

```

The missing row formation energy is slightly negative. The magnitude of the formation energy is pretty small, but just slightly bigger than the typical convergence errors observed, so we should cautiously conclude that the reconstruction is favorable for Au(110). We made a lot of shortcuts in computing this quantity, including using the experimental lattice constant of Au, not checking for convergence in k-points or planewave cutoff, and not checking for convergence with respect to slab thickness or number of relaxed layers.

5.3.2 Ag(110) missing row reconstruction

6                                       [1,0,1],
7                                       [1,1,0]],
8                               size=(1,1,1),
9                               symbol='Ag')
10
11 with jasp('bulk/Ag-fcc',
12         xc='PBE',
13         encut=350,
14         kpts=(12,12,12),
15         atoms=atoms) as calc:
16     calc.calculate()

```

Analysis of energies

```

1  from jasp import *
2
3  with jasp('surfaces/Ag-110') as calc:
4      slab = calc.get_atoms()
5      eslab = slab.get_potential_energy()
6

```

```

7  with jasp('surfaces/Ag-110-missing-row') as calc:
8      missingrow = calc.get_atoms()
9      emissingrow = missingrow.get_potential_energy()
10
11  with jasp('bulk/Ag-fcc') as calc:
12      bulk = calc.get_atoms()
13      ebulk = bulk.get_potential_energy()
14
15  print 'natoms slab'      = {0}'.format(len(slab))
16  print 'natoms missing row = {0}'.format(len(missingrow))
17  print 'natoms bulk'      = {0}'.format(len(bulk))
18
19  print 'dE = {0:1.3f} eV'.format(emissingrow + ebulk - eslab)

```

```

natoms slab      = 12
natoms missing row = 11
natoms bulk      = 1
dE = -0.008 eV

```

For Ag(110), the missing row formation energy is practically thermoneutral, i.e. not that favorable. This energy is so close to 0eV, that we cannot confidently say whether the reconstruction is favorable or not. Experimentally, the reconstruction is not seen on very clean Ag(110) although it is reported that some adsorbates may induce the reconstruction.⁶⁷

5.4 Work function

To get the work function, we need to have the local potential. this is not written by default in VASP, and we have to tell it to do that with the `LVTOT` and `LVHAR` keywords.

```

1  from jasp import *
2  import matplotlib.pyplot as plt
3
4  with jasp('surfaces/Al-slab-relaxed') as calc:
5      atoms = calc.get_atoms()
6
7  with jasp('surfaces/Al-slab-locpot',
8          xc='PBE',
9          kpts=(6,6,1),
10         encut=350,
11         lvtot=True, # write out local potential
12         lvhar=True, # write out only electrostatic potential, not xc pot
13         atoms=atoms) as calc:
14
15     calc.calculate()
16     ef = calc.get_fermi_level()
17
18     atoms = calc.get_atoms()
19
20     x,y,z,lp = calc.get_local_potential()
21
22     nx, ny, nz = lp.shape
23
24     axy = np.array([np.average(lp[:, :, z]) for z in range(nz)])
25     # setup the x-axis in realspace
26     uc = atoms.get_cell()
27     xaxis = np.linspace(0, uc[2][2], nz)
28
29     plt.plot(xaxis, axy)
30     plt.plot([min(xaxis), max(xaxis)], [ef, ef], 'k:')

```

```

31 plt.savefig('images/Al-wf.png')
32
33 ind = (xaxis > 0) & (xaxis < 5)
34 wf = np.average(axy[ind]) - ef
35 print ' The workfunction is {0:1.2f} eV'.format(wf)

```

The workfunction is 4.04 eV

The workfunction of Al is listed as 4.08 at <http://hyperphysics.phy-astr.gsu.edu/hbase/tables/photoelec.htm>

Figure 51: xy averaged local electrostatic potential of an Al(111) slab.

5.5 Surface energy

The easiest way to calculate surface energies is from this equation:

$$\sigma = \frac{1}{2} (E_{slab} - \frac{N_{slab}}{N_{bulk}} E_{bulk})$$

where E_{slab} is the total energy of a symmetric slab (i.e. one with inversion symmetry, and where both sides of the slab have been relaxed), E_{bulk} is the total energy of a bulk unit cell, N_{slab} is the number of atoms in the slab, and N_{bulk} is the number of atoms in the bulk unit cell. One should be sure that the bulk energy is fully converged with respect to k -points, and that the slab energy is also converged with respect to k -points. The energies should be compared at the same cutoff energies. The idea is then to increase the thickness of the slab until the surface energy σ converges.

Figure 52: Schematic figure illustrating the calculation of a surface energy.

Unfortunately, this approach does not always work. The bulk system is treated subtly different than the slab system, particularly in the z -direction where the vacuum is (where typically only one k -point is used in slabs). Consequently, the k -point sampling is not equivalent in the two systems, and one can in general expect some errors due to this, with the best case being cancellation of the errors due to total k -point convergence. In the worst case, one can get a linear divergence in the surface energy with slab thickness.⁶⁸

A variation of this method that usually results in better k -point error cancellation is to calculate the bulk unit cell energy using the slab unit cell with no vacuum space, with the same k -point mesh in the x and y directions, but with increased k -points in the z -direction. Thus, the bulk system and slab system have the same Brillouin zone in at least two dimensions. This maximizes the cancellation of k -point errors, but still does not guarantee convergence of the surface energy, as discussed in.^{68;69}

For quick estimates of the surface energy, one of the methods described above is likely sufficient. The advantage of these methods is the small number of calculations required to obtain the estimate, one needs only a bulk calculation (which must be done anyhow to get the bulk lattice constant to create the slab), and a slab calculation that is sufficiently thick to get the estimate. Additional calculations are only required to test the convergence of the surface energy.

An alternative method for calculating surface energies that does not involve an explicit bulk calculation follows Ref.⁶⁹ The method follows from equation (ref{eq:se}) where for a N -atom slab, in the limit of $N \rightarrow \infty$,

$$E_{slab} \approx 2\sigma + \frac{N_{slab}}{N_{bulk}} E_{bulk}$$

Then, we can estimate E_{bulk} by plotting the total energy of the slab as a function of the slab thickness.

$$\sigma = \lim_{N \rightarrow \infty} \frac{1}{2} (E_{slab}^N - N \Delta E_N)$$

$$\text{where } \Delta E_N = E_{slab}^N - E_{slab}^{N-1}.$$

We will examine this approach here. We will use unrelaxed slabs for computational efficiency.

```

1  from jasp import *
2  from ase.lattice.surface import fcc111
3  import matplotlib.pyplot as plt

nlayers = 7 sigma = 0.580 eV/atom
nlayers = 8 sigma = 0.321 eV/atom
nlayers = 9 sigma = 0.593 eV/atom
nlayers = 10 sigma = 0.402 eV/atom

```

Figure 53: Surface energy of an Al(111) slab as a function of thickness.

One reason for the oscillations may be quantum size effects.⁷⁰ In⁷¹ the surface energy of Cu(111) is reported as 0.48 eV/atom, or 1.36 J/m². Here is an example showing a conversion between these two units. We use ase to compute the area of the unit cell from the norm of the cross-product of the vectors defining the surface unit cell.

```

1 from ase.lattice.surface import fcc111
2 from ase.units import J, m
3 import numpy as np
4
5 slab = fcc111('Cu', size=(1,1,3), vacuum=10.0)
6 cell = slab.get_cell()
7
8 area = np.linalg.norm(np.cross(cell[0], cell[1]))
9
10 sigma = 0.48 #eV/atom
11
12 print 'sigma = {0} J/m^2'.format(sigma/area/(J/m**2))

```

sigma = 1.3628146074 J/m^2

5.5.1 Advanced topics in surface energy

The surface energies can be used to estimate the shapes of nanoparticles using a Wulff construction. See⁷² for an example of computing Mo₂C surface energies and particle shapes, and⁷³ for an example of the influence of adsorbates on surface energies and particle shapes of Cu.

For a classic paper on trends in surface energies see⁷⁴.

5.6 Dipole correction

A subtle problem can arise when an adsorbate is placed on one side of a slab with periodic boundary conditions, which is currently the common practice. The problem is that this gives the slab a dipole moment. The array of dipole moments created by the periodic boundary conditions generates an electric field that can distort the electron density of the slab and change the energy. The existence of this field in the vacuum also makes the zero-potential in the vacuum ill-defined, thus the work function is not well-defined. One solution to this problem is to use slabs with adsorbates on both sides, but then very thick (eight to ten layers) slabs must be used to ensure the adsorbates do not interact through the slab. An alternative solution, the dipole correction scheme, was developed by Neugebauer and Scheffler⁷⁵ and later corrected by Bengtsson.⁷⁶ In this technique, an external field is imposed in the vacuum region that exactly cancels the artificial field caused by the slab dipole moment. The advantage of this approach is that thinner slabs with adsorbates on only one side can be used.

There are also literature reports that the correction is small.⁷⁷ Nevertheless, in the literature the use of this correction is fairly standard, and it is typical to at least consider the correction.

Here we will just illustrate the effect.

5.6.1 Slab with no dipole correction

```
1  # compute local potential of slab with no dipole
2  from ase.lattice.surface import fcc111, add_adsorbate
3  from jasp import *
4  import matplotlib.pyplot as plt
5  slab = fcc111('Al', size=(2,2,2), vacuum=10.0)
6  add_adsorbate(slab, 'Na', height=1.2, position='fcc')
7
8  slab.center()
9
10 with jasp('surfaces/Al-Na-nodip',
11          xc='PBE',
12          encut=340,
13          kpts=(2, 2, 1),
14          lvtot=True, # write out local potential
15          lvhar=True, # write out only electrostatic potential, not xc pot
16          atoms=slab) as calc:
17      calc.calculate()
```

None

5.6.2 Slab with a dipole correction

Note this takes a considerably longer time to run than without a dipole correction! In VASP there are several levels of dipole correction to apply. You can use the **IDIPOL** tag to turn it on, and specify which direction to apply it in (1= x , 2= y , 3= z , 4= (x, y, z)). This simply corrects the total energy and forces. It does not change the contents of LOCPOT. For that, you have to also set the **LDIPOL** and **DIPOL** tags. It is not efficient to set all three at the same time for some reason. The VASP manual recommends you first set IDIPOL to get a converged electronic structure, and then set LDIPOL to True, and set the center of electron density in DIPOL. That makes these calculations a multistep process, because we must run a calculation, analyze the charge density to get the center of charge, and then run a second calculation.

```

1  # compute local potential with dipole calculation on
2  from ase.lattice.surface import fcc111, add_adsorbate
3  from jasp import *
4
5  slab = fcc111('Al', size=(2, 2, 2), vacuum=10.0)
6  add_adsorbate(slab, 'Na', height=1.2, position='fcc')
7
8  slab.center()
9
10 with jasp('surfaces/Al-Na-dip',
11          xc='PBE',
12          encut=340,
13          kpts=(2, 2, 1),
14          idipol=3, # only along z-axis
15          lvtot=True, # write out local potential
16          lvhar=True, # write out only electrostatic potential, not xc pot
17          atoms=slab) as calc:
18
19     calc.calculate()
20
21     x, y, z, cd = calc.get_charge_density()
22     n0, n1, n2 = cd.shape
23     nelements = n0 * n1 * n2
24     voxel_volume = slab.get_volume() / nelements
25     total_electron_charge = cd.sum() * voxel_volume
26
27     electron_density_center = np.array([(cd * x).sum(),
28                                         (cd * y).sum(),
29                                         (cd * z).sum()])
30     electron_density_center *= voxel_volume
31     electron_density_center /= total_electron_charge
32
33     print 'electron-density center = {0}'.format(electron_density_center)
34     uc = slab.get_cell()
35
36     # get scaled electron charge density center
37     sedc = np.dot(np.linalg.inv(uc.T), electron_density_center.T).T
38
39     calc.clone('surfaces/Al-Na-dip-step2')
40
41 with jasp('surfaces/Al-Na-dip-step2',
42          ldipol=True, dipol=sedc) as calc:
43     calc.calculate()

```

5.6.3 Comparing no dipole correction with a dipole correction

To see the difference in what the dipole correction does, we now plot the potentials from each calculation.

```

1  from jasp import *
2  import matplotlib.pyplot as plt
3
4  with jasp('surfaces/Al-Na-nodip') as calc:
5      atoms = calc.get_atoms()
6
7      x, y, z, lp = calc.get_local_potential()
8      nx, ny, nz = lp.shape
9
10     axy_1 = [np.average(lp[:, :, z]) for z in range(nz)]
11     # setup the x-axis in realspace
12     uc = atoms.get_cell()
13     xaxis_1 = np.linspace(0, uc[2][2], nz)

```

```

14
15     e1 = atoms.get_potential_energy()
16
17 with jasp('surfaces/Al-Na-dip-step2') as calc:
18     atoms = calc.get_atoms()
19
20     x, y, z, lp = calc.get_local_potential()
21     nx, ny, nz = lp.shape
22
23     axy_2 = [np.average(lp[:, :, z]) for z in range(nz)]
24     # setup the x-axis in realspace
25     uc = atoms.get_cell()
26     xaxis_2 = np.linspace(0, uc[2][2], nz)
27
28     ef2 = calc.get_fermi_level()
29     e2 = atoms.get_potential_energy()
30
31 print 'The difference in energy is {0} eV.'.format(e2-e1)
32
33 plt.plot(xaxis_1, axy_1, label='no dipole correction')
34 plt.plot(xaxis_2, axy_2, label='dipole correction')
35 plt.plot([min(xaxis_2), max(xaxis_2)], [ef2, ef2], 'k:', label='Fermi level')
36 plt.xlabel('z ($\text{\AA}$)')
37 plt.ylabel('xy-averaged electrostatic potential')
38 plt.legend(loc='best')
39 plt.savefig('images/dip-vs-nodip-esp.png')

```

The difference in energy is 0.006391 eV.

Figure 54: Comparison of the electrostatic potentials with a dipole correction and without it.

The key points to notice in this figure are:

1. The two deep dips are where the atoms are.

2. Without a dipole correction, the electrostatic potential never flattens out. there is near constant slope in the vacuum region, which means there is an electric field there.
3. With a dipole moment the potential is flat in the vacuum region, except for the step jump near 23 Å.
4. The difference between the Fermi level and the flat vacuum potential is the work function.
5. The difference in energy with and without the dipole correction here is small.

5.7 Adsorption energies

5.7.1 Simple estimate of the adsorption energy

Calculating an adsorption energy amounts to computing the energy of the following kind of reaction:

There are many variations of this idea. The slab may already have some adsorbates on it, the slab may reconstruct on adsorption, the gas-phase molecule may or may not dissociate, and the products may or may not stick to the surface. We have to decide where to put the adsorbates, i.e. what site to put them on, and some sites will be more stable than others. We will consider the dissociative adsorption of O₂ on three sites of a Pt(111) slab. We will assume the oxygen molecule has split in half, and that the atoms have moved far apart. We will model the oxygen coverage at 0.25 ML, which means we need to use a 2 × 2 surface unit cell. For computational speed, we will freeze the slab, but allow the adsorbate to relax.

$$\Delta H_{ads}(eV/O) = E_{slab+O} - E_{slab} - 0.5 * E_{O_2}$$

31
32 print 'Hads (fcc)      = {0} eV/0'.format(Hads_fcc)
33 print 'Hads (hcp)      = {0} eV/0'.format(Hads_hcp)
34 print 'Hads (bridge)   = {0} eV/0'.format(Hads_bridge)

```

```

Hads (fcc)      = -1.0384925 eV/0
Hads (hcp)      = -0.5986145 eV/0
Hads (bridge)   = -1.0384575 eV/0

```

You can see the hcp site is not as energetically favorable as the fcc site. Interestingly, the bridge site seems to be as favorable as the fcc site. This is not correct, and to see why, we have to look at the final geometries of each calculation. First the fcc (Figure 55 and hcp (Figure 56 sites, which look like we expect.

Figure 55: Final geometry of the fcc site.

Figure 56: Final geometry of the hcp site.

The bridge site (Figure 57, however, is clearly not at a bridge site!

Figure 57: Final geometry of the bridge site. You can see that the oxygen atom ended up in the fcc site.

Let us see what the original geometry and final geometry for the bridge site were. The POSCAR contains the initial geometry (as long as you haven't copied CONTCAR to POSCAR), and the CONTCAR contains the final geometry.

```

1 from ase.io import read, write
2
3 atoms = read('surfaces/Pt-slab-0-bridge/POSCAR')
4 write('images/Pt-o-bridge-ori.png', atoms, show_unit_cell=2)
5
6 atoms = read('surfaces/Pt-slab-0-bridge/CONTCAR')
7 write('images/Pt-o-bridge-final.png', atoms, show_unit_cell=2)

```

Figure 58: Initial geometry of the bridge site. It is definitely on the bridge.

Figure 59: Final geometry of the bridge site. It has fallen into the fcc site.

You can see the problem. We should not call the adsorption energy from this calculation a bridge site adsorption energy because the O atom is actually in an fcc site! This kind of result can happen with relaxation, and you should always check that the result you get makes sense. Next, we consider how to get a bridge site adsorption energy by using constraints.

Some final notes:

1. We did not let the slabs relax in these examples, and allowing them to relax is likely to have a big effect on the adsorption energies. You have to decide how many layers to relax, and check for convergence with respect to the number of layers.
2. The slabs were pretty thin. It is typical these days to see slabs that are 4-5 or more layers thick.

3. We did not consider how well converged the calculations were with respect to k -points or [ENCUT](#).
4. We did not consider the effect of the error in O_2 dissociation energy on the adsorption energies.
5. We did not consider coverage effects (see [Coverage dependence](#)).

Adsorption on bridge site with constraints To prevent the oxygen atom from sliding down into the fcc site, we have to constrain it so that it only moves in the z -direction. This is an artificial constraint; the bridge site is only metastable. But there are lots of reasons you might want to do this anyway. One is the bridge site is a transition state for diffusion between the fcc and hcp sites. Another is to understand the role of coordination in the adsorption energies. We use a `ase.constraints.FixScaled` constraint in ase to constrain the O atom so it can only move in the z -direction (actually so it can only move in the direction of the third unit cell vector, which only has a z -component).

```

1  from jasp import *
2
3  from ase.lattice.surface import fcc111, add_adsorbate
4  from ase.constraints import FixAtoms, FixScaled
5  from ase.io import write
6
7  atoms = fcc111('Pt', size=(2,2,3), vacuum=10.0)
8
9  # note this function only works when atoms are created by the surface module.
10 add_adsorbate(atoms, 'O', height=1.2, position='bridge')
11 constraint1 = FixAtoms(mask=[atom.symbol != 'O' for atom in atoms])
12 # fix in xy-direction, free in z. actually, freeze movement in surface
13 # unit cell, and free along 3rd lattice vector
14 constraint2 = FixScaled(atoms.get_cell(), 12, [True, True, False])
15
16 atoms.set_constraint([constraint1, constraint2])
17 write('images/Pt-O-bridge-constrained-initial.png', atoms, show_unit_cell=2)
18 print 'Initial O position: {0}'.format(atoms.positions[-1])
19
20 with jasp('surfaces/Pt-slab-O-bridge-xy-constrained',
21          xc='PBE',
22          kpts=(4,4,1),
23          encut=350,
24          ibrion=2,
25          nsw=25,
26          atoms=atoms) as calc:
27     e_bridge = atoms.get_potential_energy()
28
29 write('images/Pt-O-bridge-constrained-final.png', atoms, show_unit_cell=2)
30 print 'Final O position : {0}'.format(atoms.positions[-1])
31
32 # now compute Hads
33 with jasp('surfaces/Pt-slab') as calc:
34     atoms = calc.get_atoms()
35     e_slab = atoms.get_potential_energy()
36
37
38 with jasp('molecules/O2-sp-triplet-350') as calc:
39     atoms = calc.get_atoms()
40     e_O2 = atoms.get_potential_energy()
41
42 Hads_bridge = e_bridge - e_slab - 0.5*e_O2

```

```
43  
44 print 'Hads (bridge) = {0:1.3f} eV/0'.format(Hads_bridge)
```

You can see that only the z -position of the O atom changed. Also, the adsorption energy of O on the bridge site is **much** less favorable than on the fcc or hcp sites.

Figure 60: Initial state of the O atom on the bridge site.

Figure 61: Final state of the constrained O atom, still on the bridge site.

5.7.2 Coverage dependence

The adsorbates on the surface can interact with each other which results in coverage dependent adsorption energies.⁷⁸ Coverage dependence is not difficult to model; we simply compute adsorption energies in different size unit cells, and/or with different adsorbate configurations. Here we consider dissociative oxygen adsorption at 1ML on Pt(111) in an fcc site, which is one oxygen atom in a 1×1 unit cell.

For additional reading, see these references from our work:

- Correlations of coverage dependence of oxygen adsorption on different metals^{79;80}
- Coverage effects of atomic adsorbates on Pd(111)⁸¹
- Simple model for estimating coverage dependence⁷⁸
- Coverage effects on alloys⁸²

clean slab calculation

```
1 from jasp import *
2 from ase.lattice.surface import fcc111
3 from ase.constraints import FixAtoms
4
5 atoms = fcc111('Pt', size=(1, 1, 3), vacuum=10.0)
6 constraint = FixAtoms(mask=[True for atom in atoms])
7 atoms.set_constraint(constraint)
8
9 with jasp('surfaces/Pt-slab-1x1',
10          xc='PBE',
11          kpts=(8, 8, 1),
12          encut=350,
13          atoms=atoms) as calc:
14     slab_e = atoms.get_potential_energy()
```

fcc site at 1 ML coverage

```
1 from jasp import *
2
3 from ase.lattice.surface import fcc111, add_adsorbate
4 from ase.constraints import FixAtoms
5
6 atoms = fcc111('Pt', size=(1, 1, 3), vacuum=10.0)
7
8 # note this function only works when atoms are created by the surface module.
9 add_adsorbate(atoms, 'O', height=1.2, position='fcc')
10
11 constraint = FixAtoms(mask=[atom.symbol != 'O' for atom in atoms])
12 atoms.set_constraint(constraint)
13
14 with jasp('surfaces/Pt-slab-1x1-0-fcc',
15          xc='PBE',
16          kpts=(8, 8, 1),
17          encut=350,
18          ibrion=2,
19          nsw=25,
20          atoms=atoms) as calc:
21     calc.calculate()
```

Adsorption energy at 1ML

```
1 from jasp import *
2
3 with jasp('surfaces/Pt-slab-1x1-0-fcc') as calc:
4     atoms = calc.get_atoms()
5     e_slab_o = atoms.get_potential_energy()
6
7 # clean slab
8 with jasp('surfaces/Pt-slab-1x1') as calc:
9     atoms = calc.get_atoms()
10    e_slab = atoms.get_potential_energy()
11
12 with jasp('molecules/O2-sp-triplet-350') as calc:
13     atoms = calc.get_atoms()
14     e_O2 = atoms.get_potential_energy()
15
16 hads = e_slab_o - e_slab - 0.5*e_O2
17 print 'Hads (1ML) = {0:1.3f} eV'.format(hads)
```

$$H_{ads} (1ML) = -0.099 \text{ eV}$$

The adsorption energy is **much** less favorable at 1ML coverage than at 0.25 ML coverage! We will return what this means in [Atomistic thermodynamics effect on adsorption](#).

5.7.3 Effect of adsorption on the surface energy

There is a small point to make here about what adsorption does to surface energies. Let us define a general surface formation energy scheme like this:

Figure 62: Schematic of forming a surface with adsorbates. First we form two clean surfaces by cleaving the bulk, then allow adsorption to occur on the surfaces.

Let us presume the surfaces are symmetric, and that each surface contributes half of the energy change. The overall change in energy:

$$\Delta E = E_{slab,ads} - E_{ads} - E_{bulk}$$

where the energies are appropriately normalized for the stoichiometry. Let us rearrange the terms, and add and subtract a constant term E_{slab} .

$$\Delta E = E_{slab,ads} - E_{slab} - E_{ads} - E_{bulk} + E_{slab}$$

We defined $\gamma_{clean} = \frac{1}{2A}(E_{slab} - E_{bulk})$, and we defined $H_{ads} = E_{slab,ads} - E_{slab} - E_{ads}$ for adsorption on a single side of a slab. In this case, there are adsorbates on both sides of the slab, so $E_{slab,ads} - E_{slab} - E_{ads} = 2\Delta H_{ads}$. If we normalize by $2A$, the area for both sides of the slab, we get

$$\frac{\Delta E}{2A} = \gamma = \gamma_{clean} + \frac{H_{ads}}{A}$$

You can see here that the adsorption energy serves to stabilize, or reduce the surface energy, provided that the adsorption energy is negative.

Some final notes about the equations above:

- We were not careful about stoichiometry. As written, it is assumed there are the same number of atoms (not including the adsorbates) in the slabs and bulk, and the same

number of adsorbate atoms in the slab and E_{ads} . Appropriate normalization factors must be included if that is not true.

- It is not necessary to perform a symmetric slab calculation to determine the effect of adsorption on the surface energy! You can examine $\gamma - \gamma_{clean}$ with knowledge of only the adsorption energies!

5.8 Adsorbate vibrations

Note: you can limit the number of modes calculated with constraints (`FixAtoms` or `FixScaled`) and you use `IBRION=5`. The other settings (6, 7, 8) do not respect the selective dynamics constraints.

```

1  from jasp import *
2
3  with jasp('surfaces/Pt-slab-0-fcc') as calc:
4      calc.clone('surfaces/Pt-slab-0-fcc-vib')
5
6  with jasp('surfaces/Pt-slab-0-fcc-vib') as calc:
7      calc.set(ibrion=5, # finite differences with selective dynamics
8               nfree=2, # central differences (default)
9               potim=0.015, # default as well
10              ediff=1e-8,
11              nsw=1)
12      atoms = calc.get_atoms()
13      f,v = calc.get_vibrational_modes(0)
14
15  from ase.units import meV
16  c = 3e10 # cm/s
17  h = 4.135667516e-15 # eV*s
18
19  print 'vibrational energy = {0} eV'.format(f)
20  print 'vibrational energy = {0} meV'.format(f/meV)
21  print 'vibrational freq  = {0} 1/s'.format(f/h)
22  print 'vibrational freq  = {0} cm(-1)'.format(f/(h*c))

```

```

vibrational energy = 0.061606647 eV
vibrational energy = 61.606647 meV
vibrational freq   = 1.48964216204e+13 1/s
vibrational freq   = 496.547387346 cm(-1)

```

There are three modes for the free oxygen atom. One of them is a mode normal to the surface (the one with highest frequency). The other two are called frustrated translations. Note that we did not include the surface Pt atoms in the calculation, and this will have an effect on the result because the O atom could be coupled to the surface modes. It is typical to neglect this coupling because of the large difference in mass between O and Pt. Next we look at the difference in results when we calculate all the modes. Let us compare to `IBRION=6`.

```

1  from jasp import *
2
3  with jasp('surfaces/Pt-slab-0-fcc') as calc:
4      calc.clone('Pt-slab-0-fcc-vib-ibrion=6')
5
6  with jasp('surfaces/Pt-slab-0-fcc-vib-ibrion=6') as calc:
7      calc.set(ibrion=6, # finite differences with symmetry

```

```

8         nfree=2, # central differences (default)
9         potim=0.015, # default as well
10        ediff=1e-8,
11        nsw=1)
12    atoms = calc.get_atoms()
13
14    f,m = calc.get_vibrational_modes(0)
15    allfreq = calc.get_vibrational_modes()[0]
16
17    from ase.units import meV
18    c = 3e10 # cm/s
19    h = 4.135667516e-15 # eV*s
20
21    print 'For mode 0:'
22    print 'vibrational energy = {0} eV'.format(f)
23    print 'vibrational energy = {0} meV'.format(f/meV)
24    print 'vibrational freq  = {0} 1/s'.format(f/h)
25    print 'vibrational freq  = {0} cm(-1)'.format(f/(h*c))

```

```

For mode 0:
vibrational energy = 0.063537929 eV
vibrational energy = 63.537929 meV
vibrational freq  = 1.53634035507e+13 1/s
vibrational freq  = 512.113451691 cm(-1)

```

Note that now there are 39 modes, which is $3*N$ where $N=13$ atoms in the unit cell. Many of the modes are low in frequency, which correspond to slab modes that are essentially phonons. The O frequencies are not that different from the previous calculation (497 vs 512 cm^{-1}). This is why it is common to keep the slab atoms frozen.

Calculating these results took $39*2$ finite differences. It took about a day to get these results on a single CPU. It pays to use constraints to minimize the number of these calculations.

5.8.1 Vibrations of the bridge site

```

1  from jasp import *
2  from ase.constraints import FixAtoms
3
4  with jasp('surfaces/Pt-slab-0-bridge-xy-constrained') as calc:
5      calc.clone('surfaces/Pt-slab-0-bridge-vib')
6      atoms = calc.get_atoms()
7
8  del atoms.constraints
9  constraint = FixAtoms(mask=[atom.symbol != 'O' for atom in atoms])
10 atoms.set_constraint([constraint])
11
12 with jasp('surfaces/Pt-slab-0-bridge-vib') as calc:
13     calc.set(ibrion=5, # finite differences with selective dynamics
14            nfree=2, # central differences (default)
15            potim=0.015, # default as well
16            ediff=1e-8,
17            nsw=1)
18     atoms.set_calculator(calc) # reset atoms
19     atoms.get_potential_energy()
20     #print calc.get_vibrational_frequencies()
21     f,v = calc.get_vibrational_modes(2)
22     print calc.get_vibrational_modes()[0]
23
24 from ase.units import meV
25 c = 3e10 # cm/s

```

```

26 h = 4.135667516e-15 # eV*s
27
28 print 'vibrational energy = {0} eV'.format(f)
29 print 'vibrational energy = {0} meV'.format(f/meV)
30 print 'vibrational freq   = {0} 1/s'.format(f/h)
31 print 'vibrational freq   = {0} cm(-1)'.format(f/(h*c))

```

```

[0.065486064, 0.045079206000000004, (0.019955987+0j)]
vibrational energy = (0.019955987+0j) eV
vibrational energy = (19.955987+0j) meV
vibrational freq   = (4.82533639921e+12+0j) 1/s
vibrational freq   = (160.84454664+0j) cm(-1)

```

Note that we have one imaginary mode. This corresponds to the motion of the O atom falling into one of the neighboring 3-fold sites. It also indicates this position is not a stable minimum, but rather a saddle point. This position is a transition state for hopping between the fcc and hcp sites.

5.9 Surface Diffusion barrier

See this review⁸³ of diffusion on transition metal surfaces.

5.9.1 Standard nudged elastic band method

Here we illustrate a standard NEB method. You need an initial and final state to start with.

```

1  from jasp import *
2  from ase.neb import NEB
3  import matplotlib.pyplot as plt
4  from scipy import interpolate
5  import numpy as np
6
7  with jasp('surfaces/Pt-slab-0-fcc') as calc:
8      initial_atoms = calc.get_atoms()
9
10 with jasp('surfaces/Pt-slab-0-hcp') as calc:
11     final_atoms = calc.get_atoms()
12
13 # here is our estimated transition state. we use vector geometry to
14 # define the bridge position, and add 1.451 Ang to z based on our
15 # previous bridge calculation.
16 ts = initial_atoms.copy()
17 ts.positions[-1] = 0.5*(ts.positions[9] + ts.positions[10]) + [0,0,1.451]
18
19 # construct the band
20 images = [initial_atoms]
21 images += [initial_atoms.copy()]
22 images += [ts.copy()] # this is the TS
23
24 neb = NEB(images)
25 # Interpolate linearly the positions of these images:
26 neb.interpolate()
27
28 # now add the second half
29 images2 = [ts.copy()]
30 images2 += [ts.copy()]
31 images2 += [final_atoms]
32

```

```

33 neb2 = NEB(images2)
34 neb2.interpolate()
35
36 # collect final band. Note we do not repeat the TS in the second half
37 final_images = images + images2[1:]
38
39 with jasp('surfaces/Pt-0-fcc-hcp-neb',
40         ibrion=1,
41         nsw=90,
42         spring=-5,
43         atoms=final_images) as calc:
44
45     try:
46         images, energies = calc.get_neb()
47         p = calc.plot_neb(show=False)
48
49         # remember you are in surfaces/Pt-0-fcc-hcp-neb, so to save in
50         # the images directory you need ../../ in the path to get you
51         # back up.
52         plt.savefig('../../images/pt-o-fcc-hcp-neb.png')
53     except (VaspSubmitted, VaspQueued):
54         pass

```

Optimization terminated successfully.

Current function value: -0.575389

Iterations: 12

Function evaluations: 24

Figure 63: Energy pathway for O diffusion from an fcc to hcp site with a spline fit to determine the barrier

5.9.2 Climbing image NEB

One issue with the standard NEB method is there is no image that is exactly at the transition state. That means there is some uncertainty of the true energy of the transition state, and there

is no way to verify the transition state by vibrational analysis. The climbing image NEB method solves that problem by making one image climb to the top. You set `LCLIMB==True` in `jasp` to turn on the climbing image method. Here we use the previous calculation as a starting point and turn on the climbing image method.

```

1  # perform a climbing image NEB calculation
2  from jasp import *
3  with jasp('surfaces/Pt-0-fcc-hcp-neb') as calc:
4      calc.clone('surfaces/Pt-0-fcc-hcp-cineb')
5
6  with jasp('surfaces/Pt-0-fcc-hcp-cineb', debug=logging.DEBUG) as calc:
7      calc.set(ichain=0, lclimb=True)
8
9      images, energies = calc.get_neb(npi=4)
10     calc.plot_neb(show=False)
11 import matplotlib.pyplot as plt
12 plt.savefig('images/pt-o-cineb.png')

```

Optimization terminated successfully.

Current function value: -0.575288

Iterations: 12

Function evaluations: 24

Figure 64: Climbing image NEB

This did not do exactly what I expected. I thought there would be an image that had climbed to the top. Maybe this is an artifact of the spline fitting. More band points would probably clarify that.

5.9.3 TODO use vibrations to confirm transition state

5.10 TODO Diffusion rates with transition state theory

5.11 TODO Simulating STM images

http://cst-www.nrl.navy.mil/users/sullivan/stm_backup/stm2.html

6 Atomistic thermodynamics

Let us consider how much the Gibbs free energy of an O₂ molecule changes as a function of temperature, at 1 atm. We use the Shomate polynomials to approximate the temperature dependent entropy and enthalpy, and use the parameters from the [NIST Webbook](#) for O₂.

```
1 import numpy as np
2 import matplotlib.pyplot as plt
3 from ase.units import *
4 K = 1. #not defined in ase.units!
5
6 # Shomate parameters
7 A = 31.32234; B = -20.23531; C = 57.86644
8 D = -36.50624; E = -0.007374; F = -8.903471
9 G = 246.7945; H = 0.0
10
11 def entropy(T):
12     '''entropy returned as eV/K
13     T in K
14     '''
15     t = T/1000.
16     s = A*np.log(t) + B*t + C*(t**2)/2. + D*(t**3)/3. - E/(2.*t**2) + G
17     return s*J/mol/K
18
19 def enthalpy(T):
20     ''' H - H(298.15) returned as eV/molecule'''
21     t = T/1000.
22     h = A*t + B*(t**2)/2. + C*(t**3)/3. + D*(t**4)/4. - E/t + F - H
23     return h*kJ/mol
24
25 T = np.linspace(100,700)
26
27 G = enthalpy(T) - T*entropy(T)
28
29 plt.plot(T,G)
30 plt.xlabel('Temperature (K)')
31 plt.ylabel('$\Delta G^\circ$ (eV)')
32 plt.savefig('images/O2-mu.png')
```

Figure 65: Effect of temperature on the Gibbs free energy of an O₂ molecule at 1 atm.

This is clearly a big effect! Between 500-600K, the energy has dropped by nearly 1 eV.

```

1 import matplotlib.pyplot as plt
2 import numpy as np
3 from ase.units import *
4
5 atm = 101325*Pascal #atm is not defined in units
6 K = 1
7
8 # examine range over 10^-10 to 10^10 atm
9 P = np.logspace(-10,10)*atm
10
11 plt.semilogx(P/atm, kB*(300*K)*np.log(P/(1*atm)),label='300K')
12 plt.semilogx(P/atm, kB*(600*K)*np.log(P/(1*atm)),label='600K')
13 plt.xlabel('Pressure (atm)')
14 plt.ylabel('$\Delta G$ (eV)')
15 plt.legend(loc='best')
16 plt.savefig('images/O2-g-p.png')

```

None

Figure 66: Effects of pressure on the ideal gas Gibbs free energy of O₂.

Similarly, you can see that simply changing the pressure has a large effect on the Gibbs free energy of an ideal gas through the term: $kT \ln(P/P_0)$, and that this effect is also temperature dependent. This leads us to the final formula we will use for the chemical potential of oxygen:

$$\mu_{O_2} = E_{O_2}^{DFT} + E_{O_2}^{ZPE} + \Delta\mu(T) + kT \ln(P/P_0)$$

6.1 Bulk phase stability of oxides

We will consider the effects of oxygen pressure and temperature on the formation energy of Ag₂O and Cu₂O.

In atomistic thermodynamics, we define the free energy of formation as:

$$G_f = G_{Cu_2O} - 2G_{Cu} - 0.5G_{O_2}$$

We will at this point assume that the solids are incompressible so that $p\Delta V \approx 0$, and that $S_{Cu_2O} - 2S_{Cu} \approx 0$, which leads to $G_{Cu_2O} - 2G_{Cu} \approx E_{Cu_2O} - 2E_{Cu}$, which we directly compute from DFT. We express $G_{O_2} = \mu_{O_2} = E_{O_2}^{DFT} + E_{O_2}^{ZPE} + \Delta\mu(T) + kT \ln(P/P_0)$. In this example we neglect the zero-point energy of the oxygen molecule, and finally arrive at:

$$G_f \approx E_{Cu_2O} - 2E_{Cu} - 0.5(E_{O_2}^{DFT} + \delta\mu(T) + kT \ln(P/P_0))$$

Which, after grouping terms is:

$$G_f \approx E_{Cu_2O} - 2E_{Cu} - 0.5(E_{O_2}^{DFT}) - 0.5 * \Delta\mu_{O_2}(P, T)$$

with $\Delta\mu_{O_2}(P, T) = \delta\mu(T) + kT \ln(P/P_0)$. We get $\delta\mu(T)$ from the Janaf Tables, or the NIST Webbook.

You will recognize in this equation the standard formation energy we calculated in [Metal oxide oxidation energies](#) plus a correction for the non standard state pressure and temperature ($\Delta\mu_{O_2}(P, T) = 0$ at standard state).

$$G_f \approx H_f - 0.5 * \Delta\mu_{O_2}(P, T)$$

The formation energy of Cu₂O is -1.9521 eV/formula unit. The formation energy for Ag₂O is -0.99 eV/formula unit. Let us consider what temperature the oxides decompose at a fixed oxygen pressure of 1×10^{-10} atm. We need to find the temperature where:

$$H_f = 0.5 * \Delta\mu_{O_2}(P, T)$$

which will make the formation energy be 0.

Figure 69: Dependence of the formation energy on the oxygen chemical potential.

This graph shows graphically the $\Delta\mu_{O_2}$ required to make the metal more stable than the oxide. Anything less than about -2 eV will have the metal more stable. That can be achieved by any one of the following combinations (graphically estimated from Figure 67): About 500K at 1×10^{-10} atm, 600K at 1×10^{-5} atm, 900K at 1atm, etc. . .

6.2 Effect on adsorption

We now consider the question: Given a pressure and temperature, what coverage would you expect on a surface? We saw earlier that adsorption energies depend on the site and coverage. We also know the coverage depends on the pressure and temperature. Above some temperature, desorption occurs, and below some pressure adsorption will not be favorable. We seek to develop a quantitative method to determine those conditions.

We redefine the adsorption energy as:

$$\Delta G_{ads} \approx E_{slab,ads} - E_{slab} - \mu_{ads}$$

where again we neglect all contributions to the free energy of the slabs from vibrational energy and entropy, as well as configurational entropy if that is relevant. That leaves only the pressure and temperature dependence of the adsorbate, which we treat in the ideal gas limit.

We expand μ_{ads} as $E_{ads} + \Delta\mu(T, p)$, and thus:

$$\Delta G_{ads} \approx E_{slab,ads} - E_{slab} - E_{ads} - \Delta\mu(T, p)$$

or

$$\Delta G_{ads} \approx \Delta H_{ads} - \Delta\mu(T, p)$$

where ΔH_{ads} is the adsorption energy we defined earlier. Now we can examine the effect of $\Delta\mu(T, p)$ on the adsorption energies. We will use the adsorption energies for the oxygen on Pt(111) system we computed earlier:

Table 5: Adsorption site dependence of adsorption energies of oxygen on Pt(111).

system	$\Delta H(eV/O)$
fcc (0.25 ML)	-1.04
hcp (0.25 ML)	-0.60
bridge (0.25 ML)	-0.49

Figure 70: Effect of oxygen chemical potential on the adsorption energy.

6.3 Atomistic therodynamics and multiple reactions

In ⁷³ we considered multiple reactions in an atomistic thermodynamic framework. Let us consider these three reactions of dissociative adsorption of hydrogen and hydrogen disulfide, and consider how to compute the reaction energy for the third reaction.

1. $H_2 + 2* \rightleftharpoons 2H*$
2. $H_2S + 2* \rightleftharpoons H* + SH*$
3. $SH* + * \rightleftharpoons S* + H*$

The reaction energy of interest is $E_{rxn} = \mu_{S*} + \mu_{H*} - \mu_{SH*}$. The question is, what are these chemical potentials? We would like them in terms of pressures and temperature, preferably of molecules that can be approximated as ideal gases. By equilibrium arguments we can say that $\mu_{H*} = \frac{1}{2}\mu_{H_2}$. It follows that at equilibrium:

$$\mu_{H*} + \mu_{SH*} = \mu_{H_2S} \text{ and } \mu_{S*} + \mu_{S*} = \mu_{SH*}.$$

From the first equation we have:

$$\mu_{SH*} = \mu_{H_2S} - \frac{1}{2}\mu_{H_2}$$

and from the second equation we have:

$$\mu_{S*} = \mu_{SH*} - \mu_{H*} = \mu_{H_2S} - \mu_{H_2}.$$

Thus, the chemical potentials of all these three adsorbed species depend on the chemical potentials of two gas-phase species. The chemical potentials of each of these gases can be defined as:

$\mu_{gas}(T, p) = E_{gas}(0K) + \delta\mu + kT \ln(p/p^0)$, as we have defined before, so that only simple DFT calculations are needed to estimate them.

7 Advanced electronic structure methods

7.1 DFT+U

[VASP manual on DFT+U](#)

7.1.1 Metal oxide oxidation energies with DFT+U

We will reconsider here the reaction (see [Metal oxide oxidation energies](#)) $2 \text{Cu}_2\text{O} + \text{O}_2 \rightleftharpoons 4 \text{CuO}$. We need to compute the energy of each species, now with DFT+U. In⁴⁸ they use a U parameter of 4 eV for Cu which gave the best agreement with the experimental value. We will also try that.

```

Reaction energy = -1.663819 eV
Corrected energy = -3.023819 eV

This is still not in quantitative agreement with the result in,⁴⁸ which at U=4 eV is about -3.14 eV (estimated from a graph). We have not applied the O₂ correction here yet. In that paper, they apply a constant shift of -1.36 eV per O₂. After we apply that correction, we agree within 0.12 eV, which is pretty good considering we have not checked for convergence.

How much does U affect the reaction energy? It is reasonable to consider how sensitive our results are to the U parameter. We do that here.

28                 ibrion=-1, #do not rerelex
29                 nsw=0)
30     atoms = calc.get_atoms()
31     cuo_energy = atoms.get_potential_energy()/(len(atoms)/2)
32
33     ## O2 #####
34     # make sure to use the same cutoff energy for the O2 molecule!
35     with jasp('molecules/O2-sp-triplet-400') as calc:
36         atoms = calc.get_atoms()
37         o2_energy = atoms.get_potential_energy()
38
39     rxn_energy = 4.0*cuo_energy - o2_energy - 2.0*cu2o_energy
40     print 'U = {0} reaction energy = {1}'.format(U,rxn_energy - 1.99)

```

```

U = 2.0 reaction energy = -3.876906
U = 4.0 reaction energy = -3.653819
U = 6.0 reaction energy = -3.397605

```

In,⁴⁸ the difference in reaction energy from U=2 eV to U=4 eV was about 0.5 eV (estimated from graph). Here we see a range of 0.48 eV from U=2 eV to U=4 eV. Note that for U=0 eV, we had a (corrected reaction energy of -3.96 eV). Overall, the effect of adding U decreases this reaction energy.

This example highlights the challenge of using an approach like DFT+U. On one hand, U has a clear effect of changing the reaction energy. On the other hand, so does the correction factor for the O₂ binding energy. In⁴⁸ the authors tried to get the O₂ binding energy correction from oxide calculations where U is not important, so that it is decoupled from the non-cancelling errors that U fixes. See⁸⁴ for additional discussion of how to mix GGA and GGA+U results.

In any case, you should be careful to use well converged results to avoid compensating for convergence errors with U.

8 Acknowledgments

I would like to thank Zhongnan Xu for sending me some examples on magnetism. Alan McGaughey and Lars Grabow for sending me some NEB examples. Matt Curnan for examples of phonons.

Many thanks to students in my class who have pointed out typos, places of confusion, etc. . . These include Bruno Calfa, Matt Curnan, Charlie Janini, Feng Cao, Gamze Gumuslu, Nicholas Chisholm, Prateek Mehta, Qiyang Duan, Shubhaditya Majumdar, Steven Illes, Wee-Liat Ong, Ye Wang, Yichun Sun, Yubing Lu, and Zhongnan Xu.

9 Appendices

9.1 Recipes

9.1.1 Modifying Atoms by deleting atoms

Sometimes it is convenient to create an Atoms object by deleting atoms from an existing object. Here is a recipe to delete all the hydrogen atoms in a molecule. The idea is to make a list of indices of which atoms to delete using list comprehension, then use list deletion to delete those indices.

```

1 import textwrap
2 from ase.data.molecules import molecule
3
4 atoms = molecule('CH3CH2OH')
5
6 # we use textwrap to
7 print textwrap.fill(str(atoms),
8                     subsequent_indent='    ')
9
10 ind2del = [atom.index for atom in atoms if atom.symbol=='H']
11 print 'Indices to delete: ', ind2del
12
13 del atoms[ind2del]
14
15 print textwrap.fill(repr(atoms),
16                     subsequent_indent='    ')

```

```

Atoms(symbols='C2OH6', positions=..., cell=[1.0, 1.0, 1.0],
      pbc=[False, False, False])
Indices to delete:  [3, 4, 5, 6, 7, 8]
Atoms(symbols='C2O', positions=..., cell=[1.0, 1.0, 1.0], pbc=[False,
False, False])

```

9.1.2 Advanced tagging

We can label atoms with integer tags to help identify them later, e.g. which atoms are adsorbates, or surface atoms, or near an adsorbate, etc... We might want to refer to those atoms later for electronic structure, geometry analysis, etc...

The method uses integer tags that are powers of two, and then uses binary operators to check for matches. & is a bitwise AND. The key to understanding this is to look at the tags in binary form. The tags [1 2 4 8] can be represented by a binary string:

```

1 = [1 0 0 0]
2 = [0 1 0 0]
4 = [0 0 1 0]
8 = [0 0 0 1]

```

So, an atom tagged with 1 and 2 would have a tag of [1 1 0 0] or a tag of 3.

```

```

Figure 74: The tagged bcc(111) structure created above.

9.1.3 Using units in ase

ase uses a base set of atomic units. Other units are defined in terms of those units, and you can easily convert to alternative units by dividing your quantity in atomic units by the units

you want.

Not too many units are defined: ['A', 'AUT', 'Ang', 'Angstrom', 'Bohr', 'C', 'Debye', 'GPa', 'Ha', 'Hartree', 'J', 'Pascal', 'Ry', 'Rydberg', 'alpha', 'cm', 'eV', 'erg', 'fs', 'kB', 'kJ', 'kcal', 'kg', 'm', 'meV', 'mol', 'nm', 's', 'second']

It is not that hard to define your own derived units though. Note these are only conversion factors. No unit algebra is enforced!

```
1 from ase.units import *
2
3 d = 1*Angstrom
4 print ' d = {0} nm'.format(d/nm)
5
6 print '1 eV = {0} Hartrees'.format(eV/Hartree)
7 print '1 eV = {0} Rydbergs'.format(eV/Rydberg)
8 print '1 eV = {0} kJ/mol'.format(eV/(kJ/mol))
9 print '1 eV = {0} kcal/mol'.format(eV/(kcal/mol))
10
11 print '1 Hartree = {0} kcal/mol'.format(1*Hartree/(kcal/mol))
12 print '1 Rydberg = {0} eV'.format(1*Rydberg/eV)
13
14 # derived units
15 minute = 60*s
16 hour = 60*minute
17
18 #convert 10 hours to minutes
19 print '10 hours = {0} minutes'.format(10*hour/minute)
```

```

d = 0.1 nm
1 eV = 0.036749 Hartrees
1 eV = 0.073499 Rydbergs
1 eV = 96.485309 kJ/mol
1 eV = 23.060542 kcal/mol
1 Hartree = 627.509541 kcal/mol
1 Rydberg = 13.605698 eV
10 hours = 600.0 minutes
```

9.1.4 Extracting parts of an array

See <http://www.scipy.org/Cookbook/BuildingArrays> for examples of making numpy arrays.

When analyzing numerical data you may often want to analyze only a part of the data. For example, suppose you have x and y data, (x =time, y =signal) and you want to integrate the data between a particular time interval. You can slice a numpy array to extract parts of it. See <http://www.scipy.org/Cookbook/Indexing> for several examples of this.

In this example we show how to extract the data in an interval. We have x data in the range of 0 to 6, and y data that is the $\cos(x)$. We want to extract the x and y data for $2 < x < 4$, and the corresponding y -data. To do this, we utilize the numpy capability of slicing with a boolean array. We also show some customization of matplotlib.

```
1 import numpy as np
2 import matplotlib as mpl
3 #http://matplotlib.sourceforge.net/users/customizing.html
4 mpl.rcParams['legend.numpoints'] = 1 #default is 2
5 import matplotlib.pyplot as plt
```

```

6
7 x = np.linspace(0,6,100)
8 y = np.cos(x)
9
10 plt.plot(x,y,label='full')
11
12 ind = (x>2) & (x<4)
13
14 subx = x[ind]
15 suby = y[ind]
16
17 plt.plot(subx,suby,'bo',label='sliced')
18 xlabel('x')
19 ylabel('cos(x)')
20 plt.legend(loc='lower right')
21 plt.savefig('images/np-array-slice.png')

```

None

Figure 75: Example of slicing out part of an array. The solid line represents the whole array, and the symbols are the array between $2 < x < 4$.

The expression $x > 2$ returns an array of booleans (True where the element of x is greater than 2, and False where it is not) equal in size to x . Similarly $x < 4$ returns a boolean array where x is less than 4. We take the logical **and** of these two boolean arrays to get another boolean array where both conditions are True (i.e. $x < 2$ and $x > 4$). This final boolean array is **True** for the part of the arrays we are interested in, and we can use it to extract the subarrays we want.

9.1.5 Statistics

Confidence intervals

```

1 import numpy as np
2 from scipy.stats.distributions import t
3
4 n = 10 #number of measurements
5 dof = n - 1 #degrees of freedom
6 avg_x = 16.1 #average measurement
7 std_x = 0.01 #standard deviation of measurements
8
9 #Find 95% prediction interval for next measurement
10
11 alpha = 1.0 - 0.95
12
13 pred_interval = t.ppf(1-alpha/2., dof) * std_x * np.sqrt(1+1./n)
14
15 s = ['We are 95%% confident the next measurement',
16      ' will be between %1.3f and %1.3f']
17 print ''.join(s) % (avg_x - pred_interval, avg_x + pred_interval)

```

We are 95% confident the next measurement will be between 16.076 and 16.124

9.1.6 Curve fitting

Linear fitting

```

1 #examples of linear curve fitting using least squares

9.1.10 Interpolation with splines

When you do not know the functional form of data to fit an equation, you can still fit/interpolate with splines.

```

1 # use splines to fit and interpolate data
2 from scipy.interpolate import interp1d
3 from scipy.optimize import fmin
4 import numpy as np
5 import matplotlib.pyplot as plt
6
7
8 x = np.array([ 0,      1,      2,      3,      4  ])
9 y = np.array([ 0.,     0.308,  0.55,   0.546,  0.44 ])
10
11 # create the interpolating function
12 f = interp1d(x, y, kind='cubic', bounds_error=False)
13
14 # to find the maximum, we minimize the negative of the function. We cannot just multiply f by -1, so we create a new function
15 f2 = interp1d(x, -y, kind='cubic')
16 xmax = fmin(f2, 2.5)
17
18 xfit = np.linspace(0,4)
19
20 plt.plot(x,y,'bo')
21 plt.plot(xfit, f(xfit),'r-')
22 plt.plot(xmax, f(xmax),'g*')
23 plt.legend(['data','fit','max'], loc='best', numpoints=1)

```

Figure 79: Nonlinear fit to data.

```

24 plt.xlabel('x data')
25 plt.ylabel('y data')
26 plt.title('Max point = ({0:1.2f}, {1:1.2f})'.format(float(xmax),
27                                                    float(f(xmax))))
28 plt.savefig('images/splinefit.png')

```

There are other good examples at <http://docs.scipy.org/doc/scipy/reference/tutorial/interpolate.html>

9.1.11 Interpolation in 3D

You might ask, why would I need to interpolate in 3D? Suppose you want to plot the charge density along a line through a unit cell that does not correspond to grid points? What are you to do? Interpolate. In contrast to an abundance of methods for 1D and 2D interpolation, I could not find any standard library methods for 3D interpolation. The Scipy cookbook on interpolation suggests that it should be doable with `ndimage`, but I could not figure out how to make those examples work.

The principle we will use to develop an interpolation function in 3D is called trilinear interpolation, where we use multiple linear 1D interpolations to compute the value of a point inside a cube. As developed here, this solution only applies to rectangular grids. Later we will generalize the approach. We state the problem as follows:

We know a scalar field inside a unit cell on a regularly spaced grid. In VASP these fields may be the charge density or electrostatic potential for example, and they are known on the `fft`

Figure 80: Illustration of a spline fit to data and finding the maximum point.

grids. We want to estimate the value of the scalar field at a point not on the grid, say $P=(a,b,c)$.

Solution: Find the cube that contains the point, and is defined by points P1-P8 as shown in Figure 81.

We use 1D interpolation formulas to compute the value of the scalar field at points I1 by interpolating between P1 and P2, and the value of the scalar field at I2 by interpolating between P3 and P4. In these points the only variable changing is x , so it is a simple 1D interpolation. We can then compute the value of the scalar field at I5 by interpolating between I1 and I2. We repeat the process on the top of the cube, to obtain points I3, I4 and I5. Finally, we compute the value of the scalar field at point P by interpolating between points I5 and I6. Note that the point I5 has coordinates $(a,b,z1)$ and $(a,b,z2)$, so the final interpolation is again a 1D interpolation along z evaluated at $z=c$ to get the final value of the scalar field at $P=(a,b,c)$.

42     u3 = cd[i, j+1, k]
43     u4 = cd[i+1, j+1, k]
44     u5 = cd[i, j, k+1]
45     u6 = cd[i+1, j, k+1]
46     u7 = cd[i, j+1, k+1]
47     u8 = cd[i+1, j+1, k+1]
48
49     w1 = u2 + (u2-u1)/(x2-x1)*(a-x2)
50     w2 = u4 + (u4-u3)/(x2-x1)*(a-x2)
51     w3 = w2 + (w2-w1)/(y2-y1)*(b-y2)
52     w4 = u5 + (u6-u5)/(x2-x1)*(a-x1)
53     w5 = u7 + (u8-u7)/(x2-x1)*(a-x1)
54     w6 = w4 + (w5-w4)/(y2-y1)*(b-y1)
55     w7 = w3 + (w6-w3)/(z2-z1)*(c-z1)
56     u = w7
57
58     return u
59
60 pos = atoms.get_positions()
61
62 P1 = np.array([0.0, 5.0, 5.0])
63 P2 = np.array([9.0, 5.0, 5.0])
64
65 npoints = 60
66
67 points = [P1 + n*(P2-P1)/npoints for n in range(npoints)]
68
69 R = [np.linalg.norm(p-P1) for p in points]
70
71 # interpolated line
72 icd = [interp3d(x,y,z,cd,p[0],p[1],p[2]) for p in points]
73
74 import matplotlib.pyplot as plt
75
76 plt.plot(R, icd)
77 cR = np.linalg.norm(pos[0]-P1)
78 oR = np.linalg.norm(pos[1]-P1)
79 plt.plot([cR, cR],[0, 2], 'r-') #markers for where the nuclei are
80 plt.plot([oR, oR],[0, 8], 'r-')
81 plt.xlabel('|R| ($\AA$)')
82 plt.ylabel('Charge density (e/$\AA^3$)')
83 plt.savefig('images/C0-charge-density.png')

```

To generalize this to non-cubic cells, we need to do interpolation along arbitrary vectors. The overall strategy is the same:

Find the cell that contains the point (a,b,c). compute the scaled coordinates (sa,sb,sc) of the point inside the cell. Do the interpolations along the basis vectors. Given u1 at P1(x1,y1,z1) and u2 at P2(x2,y2,z2) where (P2-P1) is a cell basis vector a, $u = u1 + sa*(u2-u1)$. There are still 7 interpolations to do.

Below is an example of this code, using a the python library bisect to find the cell.

Figure 82: An example of interpolated charge density of A CO molecule along the axis of molecule.

```

1  '''
2  3D vector interpolation in non-cubic unit cells with vector
3  interpolation.
4
5  This function should work for any shape unit cell.

93     show()

```

None

Figure 83: Interpolated charge density for a CO molecule.

9.1.12 Reading and writing data

Builtin io modules `pylab` has two convenient and powerful functions for saving and reading data, `pylab.save` and `pylab.load`.

```
1 pylab.save('pdat.dat', (x,y))
```

and later you can read these arrays back in with:

```
1 x,y = pylab.load('pdat.dat')
```

see also `pylab.csv2rec` and `pylab.loadtxt` and `pylab.savetxt`.

See <http://www.scipy.org/Cookbook/InputOutput> for examples of numpy io.

From scratch You can save data in many ways from scratch. Basically, just open a file and write data to it. Likewise, any datafile that has some structure to it can probably be read by python.

Reading a datafile with

```

#header
#ignore these lines
john, 4
robert, 5
terry, 5

```

A standard approach would be to read in all the lines, skip the first two lines, split each line (remember each line is a string) at the ‘,’ and append the first field to one variable, and append the second field to another variable as an integer. For example:

```

1 v1 = []
2 v2 = []
3 lines = open('somefile', 'r').readlines()
4
5 for line in lines[2:]: #skip the first two lines
6     fields = line.split(',')
7     v1.append(fields[0]) #names
8     v2.append(int(fields[1])) #number

```

Writing datafiles is easy too.

```

1 v1 = ['john', 'robert', 'terry']
2 v2 = [4,5,6]
3 f = open('somefile', 'w') #note 'w' = write mode
4 f.write('#header\n')
5 f.write('#ignore these lines\n')
6 for a,b in zip(v1,v2):
7     f.write('{0}, {1}\n'.format(a,b))
8 f.close()

```

Some notes:

1. opening a file in ‘w’ mode clobbers any existing file, so do that with care!

1. when writing to a file you have to add
n to each line. This is the
carriage return.

1. Manually writing and reading files is pretty tedious. Whenever possible you should use the builtin methods of numpy or pylab.

9.1.13 Integration

Numerical integrations is easy with the `numpy.trapz()` method. Use it like this: `numpy.trapz(y,x)`. Note that y comes first. y and x must be the same length.

Integration can be used to calculate average properties of continuous distributions. Suppose for example, we have a density of states, ρ as a function of energy E. We can integrate the density of states to find the total number of states:

$$N_{states} = \int \rho dE$$

or, in python:

```
1 Nstates = np.trapz(rho,E)
```

where rho is a vector that contains the density of states at each energy in the vector E (vector here means a list of numbers).

The average energy of distribution is:

$$E_{avg} = \frac{\int \rho E dE}{\int \rho dE}$$

or, in python:

```
1 e_avg = np.trapz(rho*E,E)/np.trapz(rho,E)
```

These last two examples are the zeroth and first moments of the density of states. The second moment is related to the width squared of the distribution, and the third and fourth moments are related to skewness and kurtosis of the distribution.

The nth moment is defined by:

$$m_n = \frac{\int \rho E^n dE}{\int \rho dE}$$

To get the second moment of the density of states in python, we use::

```
1 n = 2
2 mom_2 = np.trapz(rho*E**n,E)/np.trapz(rho,E)
```

9.1.14 Numerical differentiation

numpy has a function called `numpy.diff` that is similar to the one found in Matlab. It calculates the differences between the elements in your list, and returns a list that is one element shorter, which makes it unsuitable for plotting the derivative of a function.

Simple loops to define finite difference derivatives Loops in python are pretty slow (relatively speaking) but they are usually trivial to understand. In this script we show some simple ways to construct derivative vectors using loops. It is implied in these formulas that the data points are equally spaced.

```
1 import numpy as np
2 import matplotlib.pyplot as plt
3 import time
4
5 '''
6 These are the brainless way to calculate numerical derivatives. They
7 work well for very smooth data. they are surprisingly fast even up to
8 10000 points in the vector.
9 '''
10
11 x = np.linspace(0.78,0.79,100)
12 y = np.sin(x)
13 dy_analytical = np.cos(x)
14 '''
15 let us use a forward difference method:
16 that works up until the last point, where there is not
17 a forward difference to use. there, we use a backward difference.
18 '''
19
```

```

20 tf1 = time.time()
21 dyf = [0.0]*len(x)
22 for i in range(len(y)-1):
23     dyf[i] = (y[i+1] - y[i])/(x[i+1]-x[i])
24 #set last element by backwards difference
25 dyf[-1] = (y[-1] - y[-2])/(x[-1] - x[-2])
26
27 print ' Forward difference took {0:1.1f} seconds'.format(time.time() - tf1)
28
29 '''and now a backwards difference'''
30 tb1 = time.time()
31 dyb = [0.0]*len(x)
32 #set first element by forward difference
33 dyb[0] = (y[0] - y[1])/(x[0] - x[1])
34 for i in range(1,len(y)):
35     dyb[i] = (y[i] - y[i-1])/(x[i]-x[i-1])
36
37 print ' Backward difference took {0:1.1f} seconds'.format(time.time() - tb1)
38
39 '''and now, a centered formula'''
40 tc1 = time.time()
41 dyc = [0.0]*len(x)
42 dyc[0] = (y[0] - y[1])/(x[0] - x[1])
43 for i in range(1,len(y)-1):
44     dyc[i] = (y[i+1] - y[i-1])/(x[i+1]-x[i-1])
45 dyc[-1] = (y[-1] - y[-2])/(x[-1] - x[-2])
46
47 print ' Centered difference took {0:1.1f} seconds'.format(time.time() - tc1)
48
49 '''
50 the centered formula is the most accurate formula here
51 '''
52
53 plt.plot(x,y)
54 plt.plot(x,dy_analytical,label='analytical derivative')
55 plt.plot(x,dyf,'--',label='forward')
56 plt.plot(x,dyb,'--',label='backward')
57 plt.plot(x,dyc,'--',label='centered')
58
59 plt.legend(loc='lower left')
60 plt.savefig('images/simple-diffs.png')

```

Forward difference took 0.0 seconds
Backward difference took 0.0 seconds
Centered difference took 0.0 seconds

Loops are usually not great for performance. Numpy offers some vectorized methods that allow us to compute derivatives without loops, although this comes at the mental cost of harder to understand syntax:

```

1 import numpy as np
2 import matplotlib.pyplot as plt
3
4 x = np.linspace(0,2*np.pi,100)
5 y = np.sin(x)
6 dy_analytical = np.cos(x)
7
8 # we need to specify the size of dy ahead because diff returns
9 #an array of n-1 elements
10 dy = np.zeros(y.shape,np.float) #we know it will be this size
11 dy[0:-1] = np.diff(y)/np.diff(x)
12 dy[-1] = (y[-1] - y[-2])/(x[-1] - x[-2])

```

Figure 84: Comparison of different numerical derivatives.

```

13
14
15 '''
16 calculate dy by center differencing using array slices
17 '''
18
19 dy2 = np.zeros(y.shape,np.float) #we know it will be this size
20 dy2[1:-1] = (y[2:] - y[0:-2])/(x[2:] - x[0:-2])
21 dy2[0] = (y[1]-y[0])/(x[1]-x[0])
22 dy2[-1] = (y[-1] - y[-2])/(x[-1] - x[-2])
23
24 plt.plot(x,y)
25 plt.plot(x,dy_analytical,label='analytical derivative')
26 plt.plot(x,dy,label='forward diff')
27 plt.plot(x,dy2,'k--',lw=2,label='centered diff')
28 plt.legend(loc='lower left')
29 plt.savefig('images/vectorized-diffs.png')

```

None

Figure 85: Comparison of different numerical derivatives.

If your data is very noisy, you will have a hard time getting good derivatives; derivatives tend to magnify noise. In these cases, you have to employ smoothing techniques, either implicitly by using a multipoint derivative formula, or explicitly by smoothing the data yourself, or taking the derivative of a function that has been fit to the data in the neighborhood you are interested in.

Here is an example of a 4-point centered difference of some noisy data:

```

1  import numpy as np
2  import matplotlib.pyplot as plt
3
4  x = np.linspace(0,2*np.pi,100)
5  y = np.sin(x) + 0.1*np.random.random(size=x.shape)
6  dy_analytical = np.cos(x)
7
8  #2-point formula
9  dyf = [0.0]*len(x)
10 for i in range(len(y)-1):
11     dyf[i] = (y[i+1] - y[i])/(x[i+1]-x[i])
12 #set last element by backwards difference
13 dyf[-1] = (y[-1] - y[-2])/(x[-1] - x[-2])
14
15 '''
16 calculate dy by 4-point center differencing using array slices
17
18  $\frac{y[i-2] - 8y[i-1] + 8y[i+1] - y[i+2]}{12h}$ 
19
20 y[0] and y[1] must be defined by lower order methods
21 and y[-1] and y[-2] must be defined by lower order methods
22 '''
23
24 dy = np.zeros(y.shape,np.float) #we know it will be this size
25 h = x[1]-x[0] #this assumes the points are evenly spaced!
26 dy[2:-2] = (y[0:-4] - 8*y[1:-3] + 8*y[3:-1] - y[4:])/ (12.*h)
27

```

```

28 dy[0] = (y[1]-y[0])/(x[1]-x[0])
29 dy[1] = (y[2]-y[1])/(x[2]-x[1])
30 dy[-2] = (y[-2] - y[-3])/(x[-2] - x[-3])
31 dy[-1] = (y[-1] - y[-2])/(x[-1] - x[-2])
32
33 plt.plot(x,y)
34 plt.plot(x,dy_analytical,label='analytical derivative')
35 plt.plot(x,dyf,'r-',label='2pt-forward diff')
36 plt.plot(x,dy,'k--',lw=2,label='4pt-centered diff')
37 plt.legend(loc='lower left')
38 plt.savefig('images/multipt-diff.png')

```

None

Figure 86: Comparison of 2 point and 4 point numerical derivatives.

The derivative is still noisy, but the four-point derivative is a little better than the two-pt formula.

FFT derivatives It is possible to perform derivatives using FFT:

```

1 import numpy as np
2 import matplotlib.pyplot as plt
3
4 N = 101 #number of points
5 L = 2*np.pi #interval of data
6
7 x = np.arange(0.0,L,L/float(N)) #this does not include the endpoint
8
9 #add some random noise
10 y = np.sin(x) + 0.05*np.random.random(size=x.shape)
11 dy_analytical = np.cos(x)
12
13 '''

```

```

14 http://sci.tech-archive.net/Archive/sci.math/2008-05/msg00401.html
15
16 you can use fft to calculate derivatives!
17 '''
18
19 if N % 2 == 0:
20     k = np.asarray(range(0,N/2)+[0] + range(-N/2+1,0))
21 else:
22     k = np.asarray(range(0,(N-1)/2) + [0] + range(-(N-1)/2,0))
23
24 k *= 2*np.pi/L
25
26 fd = np.fft.ifft(1.j*k * np.fft.fft(y))
27
28 plt.plot(x,y)
29 plt.plot(x,dy_analytical,label='analytical der')
30 plt.plot(x,fd,label='fft der')
31 plt.legend(loc='lower left')
32
33 plt.savefig('images/fft-der.png')

```

Figure 87: Comparison of FFT numerical derivatives.

This example does not show any major advantage in the quality of the derivative, and it is almost certain I would never remember how to do this off the top of my head.

9.1.15 NetCDF files

NetCDF is a binary, but cross-platform structured data format. The input file and output file for Dacapo is the NetCDF format. On creating a NetCDF file you must define the dimensions and variables before you can store data in them. You can create and read NetCDF files in python using one of the following modules:

Scientific.IO.NetCDF (<http://dirac.cnrs-orleans.fr/plone/software/scientificpython/>)
netCDF3 (<http://netcdf4-python.googlecode.com/svn/trunk/docs/netCDF3-module.html>)

pycdf (<http://pysclint.sourceforge.net/pycdf/>) this is a very low level module modelled after the C-api. I am not sure it is completely bug-free (I have problems with character variables)

9.1.16 python modules

the comma separated values (`csv`) module in python allows you to easily create datafiles:
csv writing:

```
1 import numpy as np
2
3 x = np.linspace(0.0,6.0,100)
4 y = np.cos(x)
5
6 import csv
7 writer = csv.writer(open("some.csv", "w"))
8 writer.writerows(zip(x,y))
```

It is not so easy to read the data back in though because the module only returns strings, so you must turn the strings back into floats (or whatever other format they should be).
csv reading:

```
1 import csv
2 reader = csv.reader(open("some.csv", 'r'), delimiter=',')
3
4 x,y = [],[]
5 for row in reader:
6     #csv returns strings that must be cast as floats
7     a,b = [float(z) for z in row]
8     x.append(a)
9     y.append(b)
```

This is almost as much work as manually reading the data though. The module is more powerful than I have shown here, so one day checkout `pydoc csv`

The `pickle` and `shelve` modules of python also offer some data storage functionality. Check them out some day too.

9.1.17 Writing and reading Excel files

Writing Excel files It is not too uncommon that it is convenient to do some analysis in Excel. We can create Excel files in python with `xlwt`. Google this module if you need to do this alot.

```
1 import numpy as np
2 import xlwt
3
4 wbk = xlwt.Workbook()
5 sheet = wbk.add_sheet('sheet 1')
6
7 volumes = np.array([13.72, 14.83, 16.0, 17.23, 18.52])
8 energies = np.array([-56.29, -56.41, -56.46, -56.46, -56.42])
9
10 for i, pair in enumerate(zip(volumes, energies)):
11     vol = pair[0]
12     energy = pair[1]
```

```

13     sheet.write(i,0,vol)
14     sheet.write(i,1,energy)
15     wbk.save('images/test-write.xls')

```

Reading Excel files We can also  read Excel files (even on Linux!) with `xlrd`. Let us read in the data we just wrote. We wrote 5 volumes to column 0, and 5 energies to column 1.

```

1  import xlrd
2  wbk = xlrd.open_workbook('images/test-write.xls')
3  sheet1 = wbk.sheet_by_name('sheet 1')
4  print sheet1.col_values(0)
5  print sheet1.col_values(1)

```

```

[13.72, 14.83, 16.0, 17.23, 18.52]
[-56.29, -56.41, -56.46, -56.46, -56.42]

```

9.1.18 TODO making movies

1. using `animate`
2. using `swftools` (`png2swf`, `pdf2swf`)

http://wiki.swftools.org/wiki/Main_Page#SWF_Tools_0.9.2..28_Current_Stable_Version..29_Documentation

9.2 Computational geometry

9.2.1 Changing coordinate systems

Let A , B , C be the unit cell vectors

$$A = A_1x + A_2y + A_3z \quad (9)$$

$$B = B_1x + B_2y + B_3z \quad (10)$$

$$C = C_1x + C_2y + C_3z \quad (11)$$

and we want to find the vector $[s_1s_2s_3]$ so that $P = s_1A + s_2B + s_3C$
if we expand this, we get:

$$\begin{aligned}
 & s_1A_1x + s_1A_2y + s_1A_3z \\
 & + s_2B_1x + s_2B_2y + s_2B_3z \\
 & + s_3C_1x + s_3C_2y + s_3C_3z = p_1x + p_2y + p_3z
 \end{aligned}$$

If we now match coefficients on x , y , and z , we can write a set of linear equations as:

$$\begin{bmatrix} A_1 & B_1 & C_1 \\ A_2 & B_2 & C_2 \\ A_3 & B_3 & C_3 \end{bmatrix} \begin{bmatrix} s_1 \\ s_2 \\ s_3 \end{bmatrix} = \begin{bmatrix} p_1 \\ p_2 \\ p_3 \end{bmatrix} \quad (12)$$

or, in standard form:

$$A^T s = p$$

and we need to solve for s as:

$$s = (A^T)^{-1} \cdot p$$

p must be a column vector, so we will have to transpose the positions provided by the atoms class, and then transpose the final result to get the positions back into row-vector form:

$$s = ((A^T)^{-1} p^T)^T$$

Here we implement that in code:

```
1 from ase.lattice.surface import fcc111
2 import numpy as np
3 np.set_printoptions(precision=3,suppress=True)
4
5 slab = fcc111('Pd',
6               a=3.92,          # Pd lattice constant
7               size=(2,2,3),    # 3-layer slab in 1x1 configuration
8               vacuum=10.0)
9
10 pos = slab.get_positions() #these positions use x,y,z vectors as a basis
11
12 # we want to see the atoms in terms of the unitcell vectors
13 newbasis = slab.get_cell()
14
15 s = np.dot(np.linalg.inv(newbasis.T),pos.T).T
16 print 'Coordinates in new basis are: \n',s
17
18 # what we just did is equivalent to the following atoms method
19 print 'Scaled coordinates from ase are: \n',slab.get_scaled_positions()
```

Coordinates in new basis are:

```
[[ 0.167  0.167  0.408]
 [ 0.667  0.167  0.408]
 [ 0.167  0.667  0.408]
 [ 0.667  0.667  0.408]
 [-0.167  0.333  0.5 ]
 [ 0.333  0.333  0.5 ]
 [-0.167  0.833  0.5 ]
 [ 0.333  0.833  0.5 ]
 [ 0.      0.      0.592]
 [ 0.5     0.      0.592]
 [ 0.      0.5     0.592]
 [ 0.5     0.5     0.592]]
```

Scaled coordinates from ase are:

```
[[ 0.167  0.167  0.408]
 [ 0.667  0.167  0.408]
 [ 0.167  0.667  0.408]
 [ 0.667  0.667  0.408]
 [ 0.833  0.333  0.5 ]
 [ 0.333  0.333  0.5 ]
 [ 0.833  0.833  0.5 ]
 [ 0.333  0.833  0.5 ]
 [ 0.      0.      0.592]
```

```
[ 0.5  0.    0.592]
[ 0.    0.5  0.592]
[ 0.5  0.5  0.592]]
```

The method shown above is general to all basis set transformations. We examine another case next. Sometimes it is nice if all the coordinates are integers. For this example, we will use the bcc primitive lattice vectors and express the positions of each atom in terms of them. By definition each atomic position should be an integer combination of the primitive lattice vectors (before relaxation, and assuming one atom is at the origin, and the unit cell is aligned with the primitive basis!)

```
1 from ase.lattice.cubic import BodyCenteredCubic
2 import numpy as np
3 bulk = BodyCenteredCubic(directions=[[1,0,0],
4                                     [0,1,0],
5                                     [0,0,1]],
6                             size=(2,2,2),
7                             latticeconstant=2.87,
8                             symbol='Fe')
9
10
11 newbasis = 2.87*np.array([[ -0.5, 0.5, 0.5],
12                           [ 0.5, -0.5, 0.5],
13                           [ 0.5, 0.5, -0.5]])
14
15 pos = bulk.get_positions()
16
17 s = np.dot(np.linalg.inv(newbasis.T),pos.T).T
18 print 'atom positions in primitive basis'
19 print s
20
21 #let us see the unit cell in terms of the primitive basis too
22 print 'unit cell in terms of the primitive basis'
23 print np.dot(np.linalg.inv(newbasis.T),bulk.get_cell().T).T
```

atom positions in primitive basis

```
[[ 0.  0.  0.]
 [ 1.  1.  1.]
 [ 0.  1.  1.]
 [ 1.  2.  2.]
 [ 1.  0.  1.]
 [ 2.  1.  2.]
 [ 1.  1.  2.]

[[ 0.  2.  2.]
 [ 2.  0.  2.]
 [ 2.  2.  0.]]
```

9.2.2 Simple distances, angles

`Scientific.Geometry` contains several useful functions for performing vector algebra including computing lengths and angles.

```
1 import numpy as np
2 from Scientific.Geometry import Vector
3
4 A = Vector([1,1,1]) #Scientific
5 a = np.array([1,1,1]) #numpy
6
7 B = Vector([0.0,1.0,0.0])
8
9 print '|A| = ',A.length() #Scientific Python way
10 print '|a| = ',np.sum(a**2)**0.5 #numpy way
11 print '|a| = ',np.linalg.norm(a) #numpy way 2
12
13 print 'ScientificPython angle = ',A.angle(B) #in radians
14 print 'numpy angle = ',np.arccos(np.dot(a/np.linalg.norm(a),B/np.linalg.norm(B)))
15
16 #cross products
17 print 'Scientific A .cross. B = ',A.cross(B)
18 print 'numpy A .cross. B = ',np.cross(A,B) #you can use Vectors in numpy
```

9.2.3 Unit cell properties

The volume of a unit cell can be calculated from $V = (a_1 \times a_2) \cdot a_3$ where a_1 , a_2 and a_3 are the unit cell vectors. It is more convenient, however, to simply evaluate that equation as the determinant of the matrix describing the unit cell, where each row of the matrix is a unit cell vector.

$$V = |\det(ucell)|$$

Why do we need to take the absolute value? The sign of the determinant depends on the handedness of the order of the unit cell vectors. If they are right-handed the determinant will be positive, and if they are left-handed the determinant will be negative. Switching any two rows will change the sign of the determinant and the handedness. `ase` implements a convenient function to get the volume of an `Atoms` object: `ase.Atoms.get_volume`.

Here are three equivalent ways to compute the unit cell volume.

```
1 import numpy as np
2
3 a1 = [2, 0, 0]
4 a2 = [1, 1, 0]
5 a3 = [0, 0, 10]
6
7 uc = np.array([a1, a2, a3])
8
9 print 'V = {} ang^3 from dot/cross'.format(np.dot(np.cross(a1,a2),a3))
10 print 'V = {} ang^3 from det'.format(np.linalg.det(uc))
11
12 from ase import Atoms
13
```

```

14 atoms = Atoms([],cell=uc) #empty list of atoms
15 print 'V = {0} ang^3 from get_volume'.format(atoms.get_volume())

```

```

V = 20 ang^3 from dot/cross
V = 20.0 ang^3 from det
V = 20.0 ang^3 from get_volume

```

9.2.4 d-spacing

If you like to set up the vacuum in your slab calculations in terms of equivalent layers of atoms, you need to calculate the d-spacing for the hkl plane you are using. The script below shows several ways to accomplish that.

```

1  import numpy as np
2  from ase.lattice.cubic import FaceCenteredCubic
3
4  ag = FaceCenteredCubic(directions=[[1,0,0],
5                                     [0,1,0],
6                                     [0,0,1]],
7                           size=(1,1,1),
8                           symbol='Ag',
9                           latticeconstant=4.0)
10
11 # these are the reciprocal lattice vectors
12 b1,b2,b3 = np.linalg.inv(ag.get_cell())
13
14 '''
15 g(111) = 1*b1 + 1*b2 + 1*b3
16
17 and |g(111)| = 1/d_111
18 '''
19 h,k,l = (1,1,1)
20 d = 1./np.linalg.norm(h*b1 + k*b2 + l*b3)
21
22 print 'd_111 spacing (method 1) = {0:1.3f} Angstroms'.format(d)
23
24 #method #2
25 hkl = np.array([h,k,l])
26 G = np.array([b1,b2,b3]) #reciprocal unit cell
27
28 '''
29 Gstar is usually defined as this matrix of dot products:
30
31 Gstar = np.array([[dot(b1,b1), dot(b1,b2), dot(b1,b3)],
32                  [dot(b1,b2), dot(b2,b2), dot(b2,b3)],
33                  [dot(b1,b3), dot(b2,b3), dot(b3,b3)]])
34
35 but I prefer the notationally more compact:
36 Gstar = G .dot. transpose(G)
37
38 then, 1/d_hkl^2 = hkl .dot. Gstar .dot. hkl
39 '''
40
41 Gstar = np.dot(G,G.T)
42
43 id2 = np.dot(hkl,np.dot(Gstar,hkl))
44
45 print 'd_111 spacing (method 2) =',np.sqrt(1/id2)
46
47 # http://books.google.com/books?id=nJHSqEseuIUC&pg=PA118&ots=YA9TBldoVH
48 # &dq=reciprocal%20metric%20tensor&pg=PA119#v=onepage

```

```

49  # &q=reciprocal%20metric%20tensor&f=false
50
51  '''Finally, many text books on crystallography use long algebraic
52  formulas for computing the d-spacing with sin and cos, vector lengths,
53  and angles. Below we compute these and use them in the general
54  triclinic structure formula which applies to all the structures.
55  '''
56  from Scientific.Geometry import Vector
57  import math
58
59  unitcell = ag.get_cell()
60  A = Vector(unitcell[0])
61  B = Vector(unitcell[1])
62  C = Vector(unitcell[2])
63
64  # lengths of the vectors
65  a = A.length()*angstroms2bohr
66  b = B.length()*angstroms2bohr
67  c = C.length()*angstroms2bohr
68
69  # angles between the vectors in radians
70  alpha = B.angle(C)
71  beta = A.angle(C)
72  gamma = A.angle(B)
73
74  print
75  print 'a    b    c    alpha beta gamma'
76  print '{0:1.3f} {1:1.3f} {2:1.3f} {3:1.3f} {4:1.3f} {5:1.3f}\n'.format(a,b,c,
77  alpha,beta,gamma)
78
79  h,k,l = (1,1,1)
80
81  from math import sin, cos
82
83  id2 = ((h**2/a**2*sin(alpha)**2
84  + k**2/b**2*sin(beta)**2
85  + l**2/c**2*sin(gamma)**2
86  +2*k*l/b/c*(cos(beta)*cos(gamma)-cos(alpha))
87  +2*h*l/a/c*(cos(alpha)*cos(gamma)-cos(beta))
88  +2*h*k/a/b*(cos(alpha)*cos(beta)-cos(gamma)))
89  /(1-cos(alpha)**2-cos(beta)**2 - cos(gamma)**2
90  +2*cos(alpha)*cos(beta)*cos(gamma))
91
92  d = 1/math.sqrt(id2)
93
94  print 'd_111 spacing (method 3) = {0}'.format(d)

```

```

a    b    c    alpha beta gamma
4.000 4.000 4.000 1.571 1.571 1.571

```

```

d_111 spacing (method 3) = 2.30940107676

```

9.3 Equations of State

The module `ase.util.eos` uses a simple polynomial equation of state to find bulk unit cell equilibrium volumes and bulk modulus. There are several other choices you could use that are more standard in the literature. Here we summarize them and provide references to the relevant literature.

9.3.1 Birch-Murnaghan

This is probably the most common equation of state used most often, and is a modification of the original Murnaghan EOS described below. A current description of the equation is in reference.⁸⁷ You can also find the equations for the Vinet and Poirier-Tarantola equations of state in that reference.

Birch-Murnaghan EOS:

$$E(\eta) = E_0 + \frac{9B_0V_0}{16}(\eta^2 - 1)^2(6 + B'_0(\eta^2 - 1) - 4\eta^2)$$

where $\eta = (V/V_0)^{1/3}$, B_0 and B'_0 are the bulk modulus and its pressure derivative at the equilibrium volume V_0 . You may find other derivations of this equation in the literature too.

Two other equations of state in that reference are the Vinet EOS:

$$E(\eta) = E_0 + \frac{2B_0V_0}{(B'_0-1)^2}(2 - (5 + 3B'_0(\eta - 1)e^{-3(B'_0-1)(\eta-1)/2}))$$

and the Poirier-Tarantola EOS:

$$E(\varrho) = E_0 + \frac{B_0V_0\varrho^2}{6}(3 + \varrho(B'_0 - 2))$$

with $\varrho = -3\ln(\eta)$.

9.3.2 Murnaghan

The equation most often used in the Murnaghan⁸⁸ equation of state is described in.⁸⁹

$$E = E_T + \frac{B_0V}{B'_0} \left[\frac{(V_0/V)^{B'_0}}{B'_0-1} + 1 \right] - \frac{V_0B_0}{B'_0-1}$$

where V is the volume, B_0 and B'_0 are the bulk modulus and its pressure derivative at the equilibrium volume V_0 . All of these are parameters that are fitted to energy vs. unit cell volume (V) data. When fitting data to this equation a guess of 2-4 for B'_0 is usually a good start.

9.3.3 Birch

The original Birch equation⁹⁰ is:

$$E = E_0 + \frac{9}{8}B_0V_0 \left(\left(\frac{V_0}{V} \right)^{\frac{2}{3}} - 1 \right)^2 + \frac{9}{16}B_0V_0(B'_0 - 4) \left(\left(\frac{V}{V_0} \right)^{2/3} - 1 \right)^3$$

9.3.4 The Anton-Schmidt Equation of state⁹¹

$$E(V) = E_\infty + \frac{BV_0}{n+1} \left(\frac{V}{V_0} \right)^{n+1} \left(\ln \frac{V}{V_0} - \frac{1}{n+1} \right)$$

where E_∞ corresponds to the energy at infinite separation, although the model they use to derive this equation breaks down at large separations so this is usually not a good estimate of the cohesive energy. n is in the range of -2.

9.3.5 Fitting data to these equations of state

To use these equations of state to find the equilibrium cell volume and bulk modulus we need a set of calculations that give us the energy of the unit cell as a function of the cell volume. We then fit that data to one of the above equations to extract the parameters we want. All of these equations of state are non-linear in the cell volume, which means you have to provide some initial guesses for the parameters.

Here we describe a strategy for getting some estimates of the parameters using a linear least squares fitting of a parabola to the data to estimate E_0 , V_0 , B and B'_0 which are used as initial guess for a non-linear least squares fit of the equation of state to the data.

The following example illustrates one approach to this problem for the Murnaghan equation of state:

```

1  '''Example of fitting the Birch-Murnaghan EOS to data'''
2
3  import numpy as np
4  import matplotlib.pyplot as plt
5  from scipy.optimize import leastsq
6
7  # raw data from 2.2.3-al-analyze-eos.py
8  v = np.array([13.72, 14.83, 16.0, 17.23, 18.52])
9  e = np.array([-56.29, -56.41, -56.46, -56.46, -56.42])
10
11 #make a vector to evaluate fits on with a lot of points so it looks smooth
12 vfit = np.linspace(min(v),max(v),100)
13
14 ### fit a parabola to the data
15 # y = ax^2 + bx + c
16 a,b,c = np.polyfit(v,e,2) #this is from pylab
17
18 '''
19 the parabola does not fit the data very well, but we can use it to get
20 some analytical guesses for other parameters.
21
22 VO = minimum energy volume, or where dE/dV=0
23 E = aV^2 + bV + c
24 dE/dV = 2aV + b = 0
25 VO = -b/2a
26
27 EO is the minimum energy, which is:
28 EO = aVO^2 + bVO + c
29
30 B is equal to VO*d^2E/dV^2, which is just 2a*VO
31
32 and from experience we know Bprime_0 is usually a small number like 4
33 '''
34
35 #now here are our initial guesses.
36 v0 = -b/(2*a)
37 e0 = a*v0**2 + b*v0 + c
38 b0 = 2*a*v0
39 bP = 4
40
41 #now we have to create the equation of state function
42 def Murnaghan(parameters,vol):
43     '''
44     given a vector of parameters and volumes, return a vector of energies.
45     equation From PRB 28,5480 (1983)
46     '''
47     EO = parameters[0]
48     BO = parameters[1]
49     BP = parameters[2]
50     VO = parameters[3]
51
52     E = EO + BO*vol/BP*((VO/vol)**BP)/(BP-1)+1) - VO*BO/(BP-1.)
53
54     return E
55
56 # and we define an objective function that will be minimized
57 def objective(pars,y,x):
58     #we will minimize this function
59     err = y - Murnaghan(pars,x)
60     return err
61
62 x0 = [e0, b0, bP, v0] #initial guesses in the same order used in the Murnaghan function

```

```

63
64 murnpars, ier = leastsq(objective, x0, args=(e,v)) #this is from scipy
65
66 #now we make a figure summarizing the results
67 plt.plot(v,e,'ro')
68 plt.plot(vfit, a*vfit**2 + b*vfit + c,'--',label='parabolic fit')
69 plt.plot(vfit, Murnaghan(murnpars,vfit), label='Murnaghan fit')
70 plt.xlabel('Volume ( $\text{\AA}^3$ )')
71 plt.ylabel('Energy (eV)')
72 plt.legend(loc='best')
73
74 #add some text to the figure in figure coordinates
75 ax = plt.gca()
76 plt.text(0.4, 0.5, 'Min volume = {0:1.2f}  $\text{\AA}^3$ '.format(murnpars[3]),
77         transform = ax.transAxes)
78 plt.text(0.4, 0.4, 'Bulk modulus = {0:1.2f} eV/ $\text{\AA}^3$  = {1:1.2f} GPa'.format(murnpars[1],
79                                     murnpars[1]*160.21773),
80         transform = ax.transAxes)
81 plt.savefig('images/a-eos.png')
82
83 np.set_printoptions(precision=3)
84 print 'initial guesses  : ', np.array(x0) #array for easy printing
85 print 'fitted parameters: ', murnpars

```

```

initial guesses  :  [-56.472  0.631  4.      16.79 ]
fitted parameters:  [-56.466  0.49   4.753  16.573]

```

You can see the Murnaghan equation of state fits the data better than the parabola.

Here is a comparison of the initial guesses and final parameters. You can see our guesses from the parabola were actually pretty good, and are the main reason we converged to a solution. If you try other guesses you will probably find the `scipy.optimize.leastsq` function does not converge.

9.4 Miscellaneous jasp/VASP tips

9.4.1 Installing jasp

You need to create an executable script named `runvasp.py` on your executable path. Here is an example script that works for both serial and parallel versions of VASP.

```

1  #!/usr/bin/env python
2  import os
3
4  serial_vasp = '/home/jkitchin/src/vasp/bin/vasp_serial_intel_mkl'
5  parallel_vasp = '/home/jkitchin/src/vasp/bin/vasp_openmpi_intel_mkl'
6
7  if 'PBS_NODEFILE' in os.environ:
8      NPROCS = len(open(os.environ['PBS_NODEFILE']).readlines())
9
10     if NPROCS == 1:
11         print 'NPROCS = ',NPROCS
12         exitcode = os.system(serial_vasp)
13     else:
14         print 'NPROCS = ',NPROCS
15         parcmd = 'mpirun -np %i %s' % (NPROCS,parallel_vasp)
16         exitcode = os.system(parcmd)
17 else:
18     exitcode = os.system(serial_vasp)
19 #end

```

Figure 88: Fitted equation of state for bulk data. The initial fitted parabola is shown to illustrate how it is useful for making initial guesses of the minimum and bulk modulus.

Then create an environment variable that points to this script. For example in `.bashrc`:

```
1 export VASP_SCRIPT=$HOME/kitchinpython/jasp/bin/run_vasp.py
```

`jasp` expects to find the POTCAR potentials in specific directories. You have two options:

1. Install the potentials in a directory and name the potential directories like this:

```
my_vasp_potentials
  potpaw
  potpaw_GGA
  potpaw_PBE
```

The `potpaw` directory contains the LDA potentials, `potpaw_GGA` contains PW91 potentials, and `potpaw_PBE` contains the PBE potentials. Then, in your `.bashrc` file set an environment variable that points to this directory. For example:

```
1 export VASP_PP_PATH=$HOME/vasp/my_vasp_potentials
```

If you already have potential directories setup with different names, you can always make symlinks with the names above that point to your directories.

9.4.2 Using a special setup

Vasp provides [special setups](#) for some elements. The following guidelines tell you what is in a potential:

No extension means the standard potential. The following extension mean:

Table 6: Meaning of extensions on POTCAR files for special setups.

extension	
<code>_h</code>	means the potential is harder than the standard (i.e. needs a higher cutoff energy)
<code>_s</code>	means the potential is softer than the standard (i.e. needs a lower cutoff energy)
<code>_sv</code>	<i>s</i> and <i>p</i> semi-core states are treated as valence states
<code>_pv</code>	<i>p</i> semi-core states are treated as valence states
<code>_d</code>	<i>d</i> semi-core states are treated as valence states

Here are some links to information in the VASP manual for the setups.

- [1st row elements](#)
- [Alkali and alkali-earth metals](#)
- [d-elements](#)
- [p-elements](#)
- [f-elements](#)

Here we show how to select the `O_sv` potential in a calculation.

```
1 from ase import Atoms, Atom
2 from jasp import *
3
4 atoms = Atoms([Atom('O',[5, 5, 5], magmom=1)],
5               cell=(6, 6, 6))
6
7 with jasp('molecules/O_sv',
8           encut=300,
9           xc='PBE',
10          ispin=2,
11          ismear=0,
12          sigma=0.001,
13          setups={'O': '_sv'}, # specifies O_sv potential
14          atoms=atoms) as calc:
15
16     print 'Total energy = {0} eV'.format(atoms.get_potential_energy())
```

Total energy = -1578.61345 eV

How do you know you got the right special setup? We can look at the first line of the POTCAR file in the calculation directory to see.

```
1 head -n 1 molecules/O_sv/POTCAR
```

```
PAW_PBE O_sv 05Jul2007
```

This shows we indeed used the O_sv setup.

9.4.3 Running jasp in parallel

jasp is smart. If you ask for more than one node, it will automatically try to run in parallel.

```
1 from jasp import *
2 JASPRC['queue.nodes']=4
3 from ase import Atom, Atoms
4 atoms = Atoms([Atom('O',[5,5,5],magmom=1)],
5               cell=(6,6,6))
6
7 with jasp('molecules/O_sv-4nodes',
8           encut=300,
9           xc='PBE',
10          ispin=2,
11          ismear=0,
12          sigma=0.001,
13          setups={'O':'_sv'}, # specifies O_sv potential
14          atoms=atoms) as calc:
15
16     print calc.calculate()
```

None

How do you know it ran on four nodes?

```
1 head molecules/O_sv-4nodes/OUTCAR
```

```
vasp.5.2.12 11Nov11 complex
```

```
executed on           LinuxIFC date 2012.08.31  09:10:10
```

```
running on      4 nodes
```

```
distr:  one band on      1 nodes,      4 groups
```

9.4.4 Exporting data json, xml, python, sqlite

jasp has some capability for representing a calculation result in an archival format. The formats currently under development are json, xml, python and sqlite. The main point of these methods is to make it easy to create archive files that are machine readable for supplementary information in publications. These are under development.

python This is code that should reconstruct the python code needed to run a particular calculation. There are some limitations, e.g. it does not currently get magnetic moments on the atoms.

```
1 from jasp import *
2
3 with jasp('bulk/alloy/cu') as calc:
4     print calc.python
```

```
from numpy import array
from ase import Atom, Atoms
from jasp import *

atoms = Atoms([Atom('Cu',[0.0, 0.0, 0.0]),
               cell = [[1.818, 0.0, 1.818],
                       [1.818, 1.818, 0.0],
                       [0.0, 1.818, 1.818]])

with jasp('bulk/alloy/cu',
          nbands = 9,
          nsw = 10,
          ibrion = 2,
          isif = 4,
          encut = 350.0,
          prec = 'Normal',
          kpts = array([13, 13, 13]),
          reciprocal = False,
          xc = 'PBE',
          txt = '-',
          gamma = False,
          atoms=atoms) as calc:
    # your code here
```

json

```
1 from jasp import *
2
3 with jasp('bulk/alloy/cu') as calc:
4     print calc.pretty_json
```

10 Python

10.1 easy_install as a user

This usually works if the directory is on your PYTHONPATH

```
easy_install -d ~/lib/python2.6/site-packages/ pymatgen
```

10.2 Integer division math gotchas

It pays to be careful when dividing by integers because you can get unexpected results if you do not know the integer division rules. In python 2.6, if you divide two integers, you get an integer! This is usually not a problem if there is no remainder in the division, e.g. $6/3=2$. But, if there is a remainder, and that remainder is important, you will lose it. Here is an example of

calculating the mole fraction of a species from integer numbers of atoms in the unit cell. If you are not careful, you get the wrong answer! You can convert (also called casting) a number to a float using the float command.

```
1 nPd = 4
2 nCu = 5
3 x_Cu = nCu/(nPd + nCu)
4 print 'x_cu = {0} (integer division)'.format(x_Cu)
5
6 # now cast as floats
7 x_Cu = float(nCu)/float(nPd + nCu)
8 print 'x_cu = {0} (float division)'.format(x_Cu)
```

```
x_cu = 0 (integer division)
x_cu = 0.555555555556 (float division)
```

Note that if one of the numbers is a float, python will automatically cast the integer as a float, and return a float.

```
1 nPd = 4
2 nCu = 5
3
4 # now cast as floats
5 x_Cu = float(nCu)/(nPd + nCu)
6 print 'x_cu = {0}'.format(x_Cu)
```

```
x_cu = 0.555555555556
```

Finally, you can tell python a number is a float by adding a decimal to it. You do not need to put a 0 after the decimal, but you can.

```
1 nPd = 4. # this is a float
2 nCu = 5
3
4 x_Cu = nCu/(nPd + nCu)
5 print 'x_cu = {0}'.format(x_Cu)
```

```
x_cu = 0.555555555556
```
